Abstract

We present in this paper an approach for computing the homogenized behavior of a medium that is a small random perturbation of a periodic reference material. The random perturbation we consider is, in a sense made precise in our work, a rare event at the microscopic level. It however affects the macroscopic properties of the material, and we indeed provide a method to compute the first and second-order corrections. To this end, we formally establish an asymptotic expansion of the macroscopic properties. Our perturbative approach shares common features with a defect-type theory of solid state physics. The computational efficiency of the approach is demonstrated.

1 Introduction

Composite materials are increasingly used in industry. For instance, modern aircrafts consist, for more than 50%, of composite materials. Generally speaking, composites are heterogeneous materials obtained by mixing two phases, a matrix and reinforcements (or inclusions). When appropriately designed, these materials outperform traditional materials, notably because they combine robustness and lightness. Their use however raises new challenges. The behavior of these materials under extreme conditions has to be predicted carefully, so as to avoid, in the worst case scenario, separation of the components (think of a plane hit by thunder). While it is possible to create an infinity of composites starting from the same elementary components, it is out of question to actually construct and experimentally test each and every possible combination. Characterizing *a priori* the properties of a given composite material, not yet synthetized or assembled, is therefore instrumental.

A brute force numerical approach, consisting in directly solving the classical boundary value problems modelling the behavior of the material, is not practical. The heterogeneities indeed often occur at a scale ϵ much finer than the overall typical lengthscale (say, 1) of

---

the material itself. A finite element mesh would, for example, need to be of size less than ϵ in order to capture the correct behavior. The number of degrees of freedom would then be proportional to ϵ^{-d} (where d denotes the dimension of the ambient physical space) and would yield, for ϵ small, a heavy computational cost one cannot necessarily afford.

The aim of homogenization is to provide a practical alternative to the brute force numerical approach. In a nutshell, homogenization consists in replacing a possibly complicated heterogeneous material with a homogeneous material sharing the same macroscopic properties. It allows for eliminating the fine scale, up to an error which is controlled by ϵ, the size of this fine scale as compared to the macroscopic size. Homogenization is a well-established theory (see [11] for a comprehensive textbook), which, in a simplified picture, can be seen as averaging partial differential equations that have highly-oscillating coefficients.

Of course, the structure of the material, and more precisely the way the constituents are combined, have a deep influence on the results of the homogenization process. The simplest possible situation is the periodic situation. At the fine scale, a unit cell is repeated in a periodic manner in all directions. Then, in simple cases (say, to be schematic and to fix the ideas, linear well-posed equations), the homogenized material is characterized only using the solution of simple problems on the unit cell, called the cell problems. The role of these cell problems is to encode the information of the micro-scale and convey it to the macro-scale. Related cases, such as pseudo-periodic materials, can be treated similarly.

As Figure 1 shows, real life materials are however not often periodic. In particular because of uncertainties and flaws in the industrial process, composites often do not exhibit a perfect periodic structure, even though it was the original plan. A suitable way to account for this is to use random modelling. Although the mathematical theory for homogenization of random materials under classical assumptions (ergodicity and stationarity) is well known, the practice is quite involved. The cell problems are defined over the whole space $\mathbb{R}^d$ and not simply on a "unit" cell. The numerical approximation of such problems using Monte-Carlo type computations is incredibly costly: the cell problems are truncated on a bounded domain, many possible realizations of the materials are considered, averages are performed. Consequently, in the context of random modelling, the benefits of homogenization over the direct attack of the original composite material are arguable.

Our line of thoughts, and the approach we try to advocate here, are based on the following two-fold observation: classical random homogenization is costly but perhaps, in a number of situations, not necessary. A more careful examination of Figure 1 indeed shows that albeit not periodic, the material is not totally random. It may probably be fairly considered as a perturbation of a periodic material. The homogenized behavior should expectedly be close to that of the underlying periodic material, up to a small error depending on the amount of randomness present.

The aim of this paper is to give a practical example of theory following the above philosophy. We introduce and study a specific model for such a randomly perturbed periodic material, which we also call a *weakly random material.* More precisely, we are interested in the homogenization of the following elliptic problem

$$\begin{cases} -\operatorname{div}\left((A_{per}(\frac{x}{\epsilon}) + b_\eta(\frac{x}{\epsilon},\omega)C_{per}(\frac{x}{\epsilon}))\nabla u_\epsilon\right) = f(x) \text{ in } \mathcal{D} \subset \mathbb{R}^d, \\ u_\epsilon = 0 \text{ on } \partial\mathcal{D}. \end{cases}$$

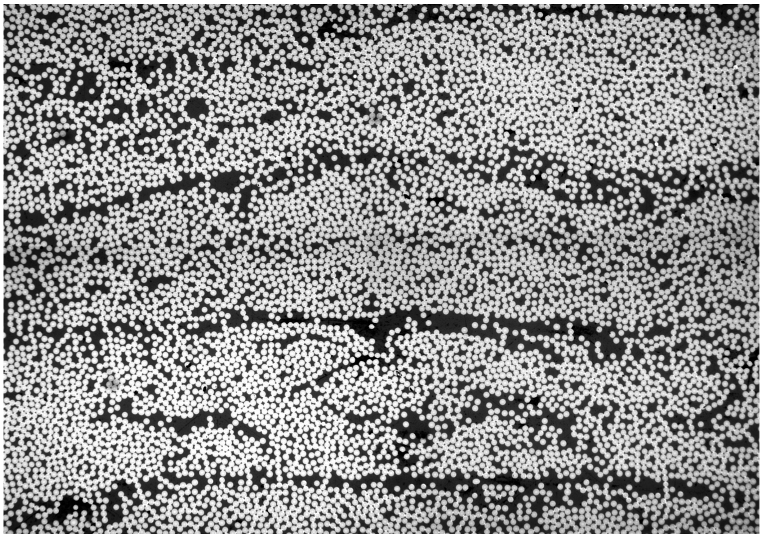

Figure 1: Two-dimensional cut of a composite material used in the aeronautics industry, extracted from [16] and reproduced with permission of the author. It is clear that this material is not periodic, yet there is some kind of an underlying periodic arrangement of the fibers.

Here the tensor A_{per} models a reference $\mathbb{Z}^d$-periodic material which is randomly perturbed by the $\mathbb{Z}^d$-periodic tensor C_{per}, the stochastic perturbation being encoded in the stationary ergodic scalar field b_η. In the present work, the law of the random variable $b_\eta(x,\cdot)$ is a Bernoulli distribution with parameter η (that is, b_η is equal to 1 with probability η and 0 with probability $1-\eta$. Using an asymptotic analysis in terms of η, we will develop an homogenization theory for $A_\eta\left(\frac{x}{\epsilon},\omega\right) = A_{per}\left(\frac{x}{\epsilon}\right) + b_\eta\left(\frac{x}{\epsilon},\omega\right) C_{per}$ based on the similar theory for $A_{per}\left(\frac{x}{\epsilon}\right)$.

In short, let us say that the main result of this article is to formally derive an expansion

$$A_\eta^* = A_{per}^* + \eta \bar{A}_1^* + \eta^2 \bar{A}_2^* + o(\eta^2),$$

where A_η^* and A_{per}^* are the homogenized tensors associated with A_η and A_{per} respectively. The first-order correction $\bar{A}_1^*$ is obtained as the limit, when $N \to \infty$, of a sequence of tensors $A_1^{*,N}$ computed on the supercell $[-\frac{N}{2},\frac{N}{2}]^d$. It is the purpose of Proposition 2 to prove the convergence of $A_1^{*,N}$. The second-order term $\bar{A}_2^*$ is likewise defined as a limit, this time up to extraction, of a sequence of tensors $A_2^{*,N}$ when $N \to \infty$. The proof of the boundedness of the sequence $A_2^{*,N}$ which implies this convergence up to extraction is not given here for it relies on long and technical calculations. Actually, we strongly believe that $A_2^{*,N}$ is a convergent sequence and that we can write the expression of the limit. We refer the reader to [1] for the details. We also stress that these corrections are achieved through purely deterministic computations.

The above setting is of course *one* possible setting where we may develop our theory, but not the only one. More general distributions are studied in [2]. Other forms of random perturbations of periodic problems, in the spirit of [7], could also be addressed. Moreover, we have deliberately considered the simplest possible equation (a scalar, linear second order elliptic equation in divergence form) to avoid any unnecessary technicalities and fundamental difficulties. Other equations could be considered, although it is not currently clear (to us, at least) how general our theory is in this respect.

With the ideas developped here (and originally introduced and further mentioned in [2, 3, 12]), we work in the footsteps of many previous contributors who have considered perturbative approaches in homogenization. In [15] and [4], a deterministic setting in which an asymptotic expansion is assumed on the properties of the material (the latter being not necessarily periodic) is studied under the name "small amplitude homogenization". In [14], the case of a Gaussian perturbation with a small variance is addressed from a mechanical point of view. Our setting here is particular, because our random perturbation has order one in amplitude. It is only *in law* that the perturbation considered is small. The corrections obtained are therefore intrinsically different from those obtained in other settings (including settings we ourselves consider elsewhere, see [1, 2]). Also, the present perturbative theory has unanticipated close connections with some classical defect-type theories used in solid state physics.

We emphasize that, contrary to what is presented in a companion paper [2] for some other distributions, the theoretical results we obtain below in the Bernoulli case are only formal. We are unfortunately unable to fully justify our manipulations except in the one-dimensional case. Nevertheless, we can prove that the terms we obtain as first-order and second-order corrections are indeed finite and well defined. Our numerical results, on the other hand, show the efficiency of the approach. They somehow constitute a proof of the definite validity of our perturbative approach, although we wish to remain cautious. Note that due to the prohibitive cost of three-dimensional random homogenization problems and the limited computing facilities we have access to, our tests are performed in dimension two.

This paper is organized as follows. For the sake of consistency and the reader's convenience, we start by recalling in Section 2 some classical results of periodic and stochastic elliptic homogenization. Then we introduce our perturbative model in Section 3, and explain how we obtain the first-order and second-order correction by means of an ergodic approximation. Our elements of proof are exposed in Section 3. Our two-dimensional numerical tests are presented in Section 4. The appendix contains explicit computations in the one-dimensional case as well as some useful technical lemmas.

Throughout this paper, and unless otherwise mentioned, K denotes a constant that depends at most on the ambient dimension d, and on the tensors A_{per} and C_{per}. The indices i and j denote indices in $[\![1, d]\!]$.

2 Some classical results of elliptic homogenization

We recall here some classical well-known results regarding linear elliptic periodic and stochastic homogenization. The reader familiar with homogenization theory can easily skip this section and directly proceed to Section 3.

2.1 Periodic homogenization

Consider A a $\mathbb{Z}^d$-periodic tensor field from $\mathbb{R}^d$ to $\mathbb{R}^{d\times d}$, that is

$$\forall k \in \mathbb{Z}^d, A(x+k) = A(x) \text{ almost everywhere in } x \in \mathbb{R}^d.$$

We assume that $A \in L^\infty(\mathbb{R}^d, \mathbb{R}^{d\times d})$ and A is coercive, which means that there exist $\lambda > 0$ and $\Lambda > 0$ such that

$$\forall \xi \in \mathbb{R}^d, \text{ a.e in } x \in \mathbb{R}^d, \ \lambda|\xi|^2 \leq A(x)\xi \cdot \xi \text{ and } |A(x)\xi| \leq \Lambda|\xi|. \tag{2.1}$$

Consider now a material occupying a bounded domain $\mathcal{O} \subset \mathbb{R}^d$. The constitutive properties of this material are supposed to be periodic, the scale of periodicity being ϵ, and we assume that these properties are given by the tensor $A_\epsilon(x) = A\left(\frac{x}{\epsilon}\right)$.

We consider the following canonical elliptic problem: $f \in L^2(\mathcal{O})$ being given, find $u_\epsilon \in H^1_0(\mathcal{O})$ solution to

$$\begin{cases} -\operatorname{div}(A_\epsilon \nabla u_\epsilon) = f \text{ in } \mathcal{O}, \\ u_\epsilon = 0 \text{ on } \partial\mathcal{O}. \end{cases} \tag{2.2}$$

A direct numerical handling of (2.2) using finite elements has a heavy computational cost since the scale ϵ of the heterogeneities requires a fine mesh. The aim of homogenization is to take the limit $\epsilon \to 0$ in (2.2) so as to replace the heterogeneous material with a homogeneous material. To this end, let us define the periodic cell problems on the unit cell $Q = [-\frac{1}{2}, \frac{1}{2}]^d$ by: $\forall i \in [\![1, d]\!]$,

$$\begin{cases} -\operatorname{div}(A(\nabla w_i + e_i)) = 0 \quad \text{in } Q, \\ w_i \ \ \mathbb{Z}^d - \text{periodic}, \end{cases} \tag{2.3}$$

where e_i is the i-th canonical vector of $\mathbb{R}^d$. Problem (2.3) has a solution unique up to the addition of a constant. Note that the number of cell problems is equal to the dimension of the space.

The homogenized tensor A^* is then given by:

$$\forall (i,j) \in [\![1, d]\!]^2, \ \ A^*_{ji} = \int_Q A(\nabla w_i + e_i) \cdot e_j. \tag{2.4}$$

Using (2.3), it also holds

$$A^*_{ji} = \int_Q A(\nabla w_i + e_i) \cdot (\nabla w_j + e_j).$$

Notice that in this periodic setting A^* is a constant matrix.

Finally, let us define the homogenized solution u_0 as the unique solution in $H^1_0(\mathcal{O})$ to

$$\begin{cases} -\operatorname{div}(A^* \nabla u_0) = f \text{ in } \mathcal{O}, \\ u_0 = 0 \text{ on } \partial\mathcal{O}. \end{cases} \tag{2.5}$$

Solving (2.3) and (2.5) is much simpler than directly solving (2.2) for the fine scale ϵ has disappeared. It is well-known (see [11] for instance) that

$$u_\epsilon \underset{\epsilon\to 0}{\to} u_0 \quad \text{in } L^2(\mathcal{O}) \tag{2.6}$$

and

$$u_\epsilon - u_0 - \epsilon \sum_{i=1}^d w_i\left(\frac{\cdot}{\epsilon}\right) \frac{\partial u_0}{\partial x_i} \underset{\epsilon\to 0}{\to} 0 \quad \text{in } H^1(\mathcal{O}). \tag{2.7}$$

The functions w_i are also called the correctors, since they allow for the *strong* convergence in (2.7). Convergences (2.6) and (2.7) show the relevance of the homogenization process: u_ϵ can be replaced by u_0 or more accurately $u_0 + \epsilon \sum_{i=1}^d w_i\left(\frac{x}{\epsilon}\right) \frac{\partial u_0}{\partial x_i}(x)$, which are easier to compute.

2.2 Stochastic homogenization

Throughout the article, $(\Omega, \mathcal{F}, \mathbb{P})$ denotes a probability space, $\mathbb{P}$ the probability measure and $\omega \in \Omega$ an event. We denote by $\mathbb{E}(X)$ the expectation of a random variable X.

We assume that the group $(\mathbb{Z}^d, +)$ acts on Ω and denote by $\tau_k, k \in \mathbb{Z}^d$, the group action. We also assume that this action is measure-preserving, that is,

$$\forall \mathcal{A} \in \mathcal{F}, \forall k \in \mathbb{Z}^d,\ \mathbb{P}(\mathcal{A}) = \mathbb{P}(\tau_k \mathcal{A}),$$

and ergodic:

$$\forall \mathcal{A} \in \mathcal{F}, (\forall k \in \mathbb{Z}^d, \mathcal{A} = \tau_k \mathcal{A}) \implies (\mathbb{P}(\mathcal{A}) = 0 \text{ or } \mathbb{P}(\mathcal{A}) = 1).$$

We call $F \in L^1_{loc}(\mathbb{R}^d, L^1(\Omega))$ stationary if

$$\forall k \in \mathbb{Z}^d,\ F(x+k, \omega) = F(x, \tau_k \omega) \text{ almost everywhere in } x \in \mathbb{R}^d \text{ and } \omega \in \Omega. \tag{2.8}$$

Notice that the notion of stationarity we use here is *discrete*: the shifts in (2.8) are assumed to be integers. This is related to our wish to connect the random problems considered with some underlying periodic problems. Notice also that for a deterministic F, stationarity amounts to $\mathbb{Z}^d$-periodicity.

Consider a stationary tensor field $A(x, \omega) \in L^\infty(\mathbb{R}^d \times \Omega, \mathbb{R}^{d \times d})$, such that (2.1) is almost surely satisfied by $A(\cdot, \omega)$, and a material occupying a bounded domain $\mathcal{O} \subset \mathbb{R}^d$ modeled by $A\left(\frac{x}{\epsilon}, \omega\right)$.

We are interested in solving, for a deterministic function f,

$$\begin{cases} -\operatorname{div}\left(A\left(\dfrac{x}{\epsilon}, \omega\right) \nabla u_\epsilon\right) = f(x) \text{ in } \mathcal{O}, \\ u_\epsilon = 0 \text{ on } \partial\mathcal{O}. \end{cases} \tag{2.9}$$

In order to describe the behavior of u_ϵ, we again need to define cell problems. Here they read (see [11]):

$$\begin{cases} -\operatorname{div}\left(A(x, \omega)(\nabla w_i + e_i)\right) = 0 \quad \text{in } \mathbb{R}^d, \\ \nabla w_i \text{ stationary}, \quad \mathbb{E}\left(\displaystyle\int_Q \nabla w_i\right) = 0. \end{cases} \tag{2.10}$$

Problem (2.10) has a solution unique up to the addition of a (possibly random) constant.

Then we define the homogenized tensor A^* by

$$\forall (i,j) \in [\![1, d]\!]^2, A^*_{ji} = \mathbb{E}\left(\int_Q A(y, \omega)(e_i + \nabla_y w_i(y, \omega)) \cdot e_j dy\right). \tag{2.11}$$

Notice that A^* is deterministic and constant throughout the domain $\mathcal{O}$. The homogenized field u_0, which gives the asymptotic behavior of u_ϵ (in a sense similar to (2.6) and (2.7)), is also deterministic. It is the unique solution in $H^1_0(\mathcal{O})$ to

$$\begin{cases} -\operatorname{div}\left(A^* \nabla u_0\right) = f \text{ in } \mathcal{O}, \\ u_0 = 0 \text{ on } \partial\mathcal{O}. \end{cases}$$

The computation of the stochastic cell problems (2.10) is not an easy task since the problems are posed in an infinite domain ($\mathbb{R}^d$) with a stationarity condition. As we have seen in the previous paragraph, when the material is periodic, the cell problems (2.10) reduce to the deterministic cell problems (2.3) which are $\mathbb{Z}^d$-periodic and can thus be computed on the unit cell Q. Consequently, when the material under consideration is a stochastic perturbation of a reference periodic material, we expect the computation of the homogenized tensor to be tractable, up to an approximation. This is our motivation for proposing a perturbative approach.

3 Homogenization of a randomly perturbed periodic material

3.1 Presentation of the model

In the stochastic framework (2.9)-(2.10)-(2.11), we now specifically consider the following tensor field in $\mathbb{R}^d \times \Omega$:

$$A_\eta(x,\omega) = A_{per}(x) + b_\eta(x,\omega) C_{per}(x). \tag{3.1}$$

Here A_{per} and C_{per} are two deterministic $\mathbb{Z}^d$-periodic tensor fields. Intuitively, A_{per} is the reference material perturbed by C_{per}. The random character of the perturbation is encoded in the stationary ergodic scalar field b_η , upon which we assume the expression

$$b_\eta(x,\omega) = \sum_{k\in\mathbb{Z}^d} \mathbb{1}_{Q+k}(x) B_\eta^k(\omega),$$

where the B_η^k are independent random variables having Bernoulli distribution with parameter η, meaning $B_\eta^k = 0$ with probability $1-\eta$ and $B_\eta^k = 1$ with probability η.

It is clear that as $\eta \to 0$ the perturbation becomes a rare event. However, the realization of this event modifies the microscopic structure of the material since it replaces, in a given cell, A_{per} with $A_{per} + C_{per}$.

We additionally assume that there exist $0 < \alpha \leq \beta$ such that for all $\xi \in \mathbb{R}^d$ and almost all $x \in \mathbb{R}^d$,

$$\alpha|\xi|^2 \leq A_{per}(x)\xi\cdot\xi, \qquad \alpha|\xi|^2 \leq \left(A_{per} + C_{per}\right)(x)\xi\cdot\xi, \tag{3.2}$$

$$|A_{per}(x)\xi| \leq \beta|\xi|, \qquad |\left(A_{per} + C_{per}\right)(x)\xi| \leq \beta|\xi|. \tag{3.3}$$

We can therefore use for every $0 \leq \eta \leq 1$ the stochastic homogenization results recalled in Section 2. The cell problems associated with (3.1) read, for $1 \leq i \leq d$,

$$\begin{cases} -\operatorname{div}\left(A_\eta(\nabla w_i^\eta + e_i)\right) = 0 \quad \text{in } \mathbb{R}^d, \\ \nabla w_i^\eta \ \text{ stationary}, \ \ \mathbb{E}\left(\int_Q \nabla w_i^\eta\right) = 0, \end{cases} \tag{3.4}$$

and the homogenized tensor A_η^* is given by

$$A_\eta^* e_i = \mathbb{E}\left(\int_Q A_\eta(\nabla w_i^\eta + e_i)\right), \ \ \text{for } 1 \leq i \leq d. \tag{3.5}$$

Throughout the rest of this paper we denote by w_i^0 the solution to the i-th cell problem (2.3) associated with A_{per}.

Because of the specific form of A_η, and more precisely because A_η converges strongly to A_{per} in $L^2(Q\times\Omega)$ as $\eta \to 0$, it is easy to see that:

Lemma 1. *When $\eta \to 0$, $A^*_\eta \to A^*_{per}$.*

Proof. Fix $1 \leq i \leq d$. We start by proving that ∇w_i^η converges strongly in $L^2(Q \times \Omega)$ to ∇w_i^0. Indeed, define $r_i^\eta = w_i^\eta - w_i^0$ solution to

$$\begin{cases} -\operatorname{div}\left(A_\eta \nabla r_i^\eta\right) = \operatorname{div}\left(b_\eta C_{per}\left(\nabla w_i^0 + e_i\right)\right) \quad \text{in } \mathbb{R}^d, \\ \nabla r_i^\eta \text{ stationary}, \quad \mathbb{E}\left(\int_Q \nabla r_i^\eta\right) = 0. \end{cases} \tag{3.6}$$

Standard cut-off and ergodicity arguments (see e.g the proof of Proposition 3.1 in [7]) show that

$$\begin{aligned} \|\nabla r_i^\eta\|_{L^2(Q\times\Omega)} &\leq \frac{1}{\alpha}\|b_\eta C_{per}\left(\nabla w_i^0 + e_i\right)\|_{L^2(Q\times\Omega)} \\ &= \frac{1}{\alpha}\|B_\eta^0\|_{L^2(\Omega)}\|C_{per}\left(\nabla w_i^0 + e_i\right)\|_{L^2(Q)} \\ &= \frac{1}{\alpha}\sqrt{\eta}\|C_{per}\left(\nabla w_i^0 + e_i\right)\|_{L^2(Q)}, \end{aligned}$$

where α is defined in (3.2), so that $\nabla w_i^\eta \underset{\eta\to 0}{\to} \nabla w_i^0$ in $L^2(Q \times \Omega)$.

Next, it is straightforward to see that A_η converges strongly to A_{per} in $L^2(Q \times \Omega)$. We deduce from these two strong convergences that

$$A^*_\eta e_i = \mathbb{E}\left(\int_Q A_\eta(x,\omega)(\nabla w_i^\eta + e_i)\right) \underset{\eta\to 0}{\to} \int_Q A_{per}(\nabla w_i^0 + e_i) = A^*_{per} e_i.$$

This concludes the proof.

□

Our goal is now to find an asymptotic expansion for A_η with respect to η up to the second order.

3.2 An ergodic approximation of the homogenized tensor

We consider a specific realization $\tilde{\omega} \in \Omega$ of the tensor A_η in the truncated domain $I_N = [-\frac{N}{2}, \frac{N}{2}]^d$, with (for simplicity) N an odd integer, and solve the following "supercell" problem:

$$\begin{cases} -\operatorname{div}\left(A_\eta(x,\tilde{\omega})(\nabla w_i^{\eta,N,\tilde{\omega}} + e_i)\right) = 0 \quad \text{in } I_N, \\ w_i^{\eta,N,\tilde{\omega}} \ (N\mathbb{Z})^d - \text{periodic}. \end{cases} \tag{3.7}$$

Then an easy adaptation of Theorem 1 of [8], stated in the continuous stationary setting, to our discrete stationary setting, shows that when N goes to infinity,

$$\frac{1}{N^d}\int_{I_N} A_\eta(x,\tilde{\omega})(\nabla w_i^{\eta,N,\tilde{\omega}}(x) + e_i)dx \text{ converges to } A^*_\eta e_i \text{ almost surely in } \tilde{\omega} \in \Omega. \tag{3.8}$$

Since $\frac{1}{N^d}\int_{I_N} A_\eta(x,\tilde{\omega})(\nabla w_i^{\eta,N,\tilde{\omega}}(x) + e_i)dx$ is the tensor obtained by periodic homogenization of the tensor $A_\eta(x,\tilde{\omega})$ in the supercell I_N, it is also well-known (see [11]) that the following bounds hold for all $(i,j) \in [\![1,d]\!]^2$:

$$\begin{aligned} \frac{1}{N^d}\left(\int_{I_N} A_\eta^{-1}(x,\tilde{\omega})dx\right)^{-1} e_i \cdot e_j &\leq \frac{1}{N^d}\int_{I_N} A_\eta(x,\tilde{\omega})(\nabla w_i^{\eta,N,\tilde{\omega}}(x) + e_i)\cdot e_j dx \\ &\leq \frac{1}{N^d}\left(\int_{I_N} A_\eta(x,\tilde{\omega})dx\right) e_i \cdot e_j. \end{aligned}$$

As a result, for all N in $2\mathbb{N}+1$, for all $0 \leq \eta \leq 1$ and almost all $\tilde{\omega}$ in Ω,

$$\left| \frac{1}{N^d} \int_{I_N} A_\eta(x,\tilde{\omega})(\nabla w_i^{\eta,N,\tilde{\omega}}(x) + e_i) \cdot e_j dx \right| \leq \beta, \tag{3.9}$$

where β is defined in (3.3). We then deduce from (3.8), (3.9) and the Lebegue dominated convergence theorem that

$$\forall 1 \leq i \leq d, \;\; A_\eta^* e_i = \lim_{N \to +\infty} \frac{1}{N^d} \mathbb{E} \left(\int_{I_N} A_\eta(x,\omega)(\nabla w_i^{\eta,N,\omega}(x) + e_i) \right) dx. \tag{3.10}$$

Remark 1. *A similar result holds for homogeneous Dirichlet and Neumann boundary conditions instead of periodic conditions in the definition (3.7) of $w_i^{\eta,N,\tilde{\omega}}$ (see [8] for more details).*

Using now the fact that b_η has a Bernoulli distribution in each cell of $\mathbb{Z}^d$, it is a simple matter to count the events and to make (3.10) more precise. We first define the set

$$\mathcal{T}_N = \left\{ k \in \mathbb{Z}^d, Q + k \subset I_N \right\} = \left[\!\left[-\frac{N-1}{2}, \frac{N-1}{2} \right]\!\right]^d. \tag{3.11}$$

The cardinal of $\mathcal{T}_N$ is of course N^d, and $\displaystyle\bigcup_{k \in \mathcal{T}_N} \{Q+k\} = I_N$.

We then have the following possible values for A_η:

- $A_\eta(x,\tilde{\omega}) = A_{per}$ with probability $(1-\eta)^{N^d}$.

  In this case $w_i^{\eta,N,\tilde{\omega}} = w_i^0$ solves the usual periodic cell problem:

  $$\begin{cases} -\operatorname{div}\left(A_{per}(\nabla w_i^0 + e_i)\right) = 0 \quad \text{in } Q, \\ w_i^0 \;\; \mathbb{Z}^d - \text{periodic}. \end{cases}$$

- $A_\eta(x,\tilde{\omega}) = A_{per} + \mathbb{1}_{\{Q+k\}} C_{per}$ for $k \in \mathcal{T}_N$, with probability $\eta(1-\eta)^{N^d-1}$.

  In this case $w_i^{\eta,N,\tilde{\omega}} = w_i^{1,k,N}$ solves the following problem, which we call here a “one defect” supercell problem:

  $$\begin{cases} -\operatorname{div}\left(\left(A_{per} + \mathbb{1}_{\{Q+k\}} C_{per}\right)\left(\nabla w_i^{1,k,N} + e_i\right)\right) = 0 \quad \text{in } I_N, \\ w_i^{1,k,N} \;\; (N\mathbb{Z})^d - \text{periodic}. \end{cases} \tag{3.12}$$

- $A_\eta(x,\tilde{\omega}) = A_{per} + \mathbb{1}_{\{Q+l\} \cup \{Q+m\}} C_{per}$ for $(l,m) \in \mathcal{T}_N$, $l \neq m$, with probability $\eta^2(1-\eta)^{N^d-2}$.

  In this case $w_i^{\eta,N,\tilde{\omega}} = w_i^{2,l,m,N}$ solves the following problem, which we call here a “two defects” supercell problem:

  $$\begin{cases} -\operatorname{div}\left(\left(A_{per} + \mathbb{1}_{\{Q+l\} \cup \{Q+m\}} C_{per}\right)\left(\nabla w_i^{2,l,m,N} + e_i\right)\right) = 0 \quad \text{in } I_N, \\ w_i^{2,l,m,N} \;\; (N\mathbb{Z})^d - \text{periodic}. \end{cases} \tag{3.13}$$

All the other possible values for A_η, which are of probability less than η^3 and which we will not use in this article, can be obtained using similar computations.

An instance of a setting with zero, one and two defects is shown in Figure 2 in the two-dimensional case of a material A_{per} consisting of a lattice of inclusions.

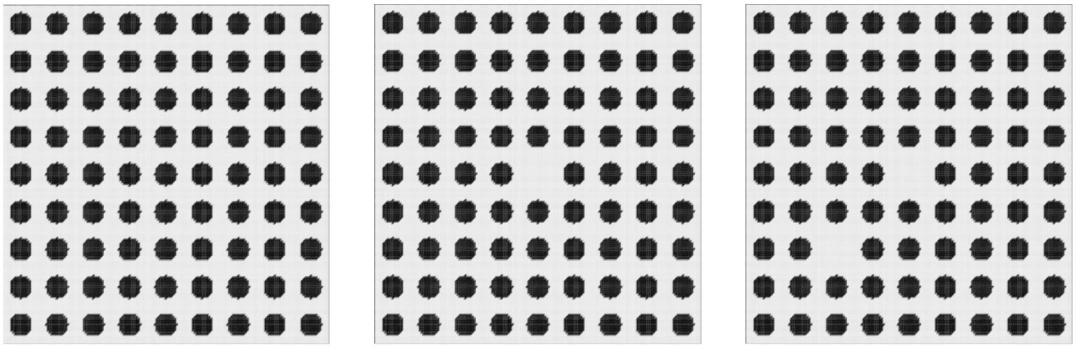

Figure 2: From left to right: zero defect, one defect and two defects.

Let us define $A_1^k = A_{per} + \mathbb{1}_{\{Q+k\}} C_{per}$ and $A_2^{l,m} = A_{per} + \mathbb{1}_{\{Q+l\}\cup\{Q+m\}} C_{per}$. Then (3.10) reads

$$\begin{aligned} A^*_\eta e_i = \lim_{N\to\infty} \Bigg(& \frac{(1-\eta)^{N^d}}{N^d} \int_{I_N} A_{per}(\nabla w_i^0 + e_i) + \sum_{k\in\mathcal{T}_N} \frac{\eta(1-\eta)^{N^d-1}}{N^d} \int_{I_N} A_1^k(\nabla w_i^{1,k,N} + e_i) \\ & + \sum_{l,m\in\mathcal{T}_N, l\neq m} \frac{\eta^2(1-\eta)^{N^d-2}}{2N^d} \int_{I_N} A_2^{l,m}(\nabla w_i^{2,l,m,N} + e_i) + \cdots \Bigg). \end{aligned}$$

It is clear, by $(N\mathbb{Z})^d$-periodicity, that $\int_{I_N} A_1^k(\nabla w_i^{1,k,N} + e_i)$ does not depend on the position $k \in \mathcal{T}_N$ of the defect. Likewise, $\int_{I_N} A_2^{l,m}(\nabla w_i^{2,l,m,N} + e_i)$ only depends on the vector $m - l$. Thus we can rewrite

$$\begin{aligned} A^*_\eta e_i = \lim_{N\to\infty} \Bigg(& (1-\eta)^{N^d} A^*_{per} e_i + \eta(1-\eta)^{N^d-1} \int_{I_N} A_1^0(\nabla w_i^{1,0,N} + e_i) \\ & + \sum_{k\in\mathcal{T}_N, k\neq 0} \frac{\eta^2(1-\eta)^{N^d-2}}{2} \int_{I_N} A_2^{0,k}(\nabla w_i^{2,0,k,N} + e_i) + \cdots \Bigg). \end{aligned} \tag{3.14}$$

This is of the form

$$\begin{aligned} A^*_\eta &= \lim_{N\to\infty} \sum_{p=0}^{N^d} \eta^p A_p^{*,N} \\ &= \lim_{N\to\infty} \left(A_0^{*,N} + \eta A_1^{*,N} + \eta^2 A_2^{*,N} + o_N(\eta^2) \right), \end{aligned} \tag{3.15}$$

where the remainder $o_N(\eta^2)$ depends on N.

Explicitly expanding the polynomials in η up to the second-order in (3.14), we obtain:

$$A_0^{*,N} = A^*_{per}, \tag{3.16}$$

$$A_1^{*,N} e_i = \int_{I_N} A_1^0(\nabla w_i^{1,0,N} + e_i) - \int_{I_N} A_{per}(\nabla w_i^0 + e_i), \tag{3.17}$$

$$A_2^{*,N} e_i = \frac{1}{2} \sum_{k \in \mathcal{T}_N, k \neq 0} \Big(\int_{I_N} A_2^{0,k} (\nabla w_i^{2,0,k,N} + e_i) - 2 \int_{I_N} A_1^0 (\nabla w_i^{1,0,N} + e_i) \\ + \int_{I_N} A_{per} (\nabla w_i^0 + e_i) \Big) \tag{3.18}$$

as the first three coefficients in (3.15).

Remark 2. *The structure of $A_p^{*,N}$ for $p \in \mathbb{N}$ is obviously related to that of the polynomial $(1-x)^p$.*

Our approach consists in formally exchanging the limits $N \to \infty$ and $\eta \to 0$ in (3.15). In the next section, we show that $A_1^{*,N}$ is a converging sequence when $N \to \infty$. The case of $A_2^{*,N}$, which is shown to be a bounded sequence and thus to converge up to extraction, is discussed in Section 3.4.

We are not able to prove, though, that $A_\eta^* - \lim\limits_{N \to \infty} (A_{per}^* - \eta A_1^{*,N} - \eta^2 A_2^{*,N}) = o(\eta^2)$ with a remainder term $o(\eta^2)$ independent of N.

Remark 3. *The expression of $A_1^{*,N}$ (and likewise $A_2^{*,N}$) is reminiscent of standard expressions in solid state theory: each of the two integrals in the definition (3.17) of $A_1^{*,N}$ scales as the volume N^d of the domain I_N, and a priori needs to be renormalized in order to give a finite limit. The difference however has a finite limit without renormalization. In solid state physics, it is common to substract a jellium, that is, a uniform background, and proceed similarly.*

3.3 Convergence of the first-order term $A_1^{*,N}$

We study here the convergence, as N goes to infinity, of $A_1^{*,N}$ defined by (3.17), and prove:

Proposition 2. *$A_1^{*,N}$ converges to a finite limit $\bar{A}_1^*$ in $\mathbb{R}^{d \times d}$ when $N \to \infty$.*

Proof. We fix (i,j) in $[\![1,d]\!]^2$ and study the convergence of $A_1^{*,N} e_i \cdot e_j$.

Let us define the adjoint problems to the cell problems (2.3):

$$\begin{cases} -\operatorname{div}\left(A_{per}^T (\nabla \tilde{w}_j^0 + e_j)\right) = 0 & \text{in } Q, \\ \tilde{w}_j^0 \ \ \mathbb{Z}^d - \text{periodic}, \end{cases} \tag{3.19}$$

where we have denoted by A_{per}^T the transposed matrix of A_{per}. Then using (3.12) and the definition of A_1^0, we have

$$\begin{aligned} \int_{I_N} A_1^0 (\nabla w_i^{1,0,N} + e_i) \cdot e_j &= \int_{I_N} A_1^0 (\nabla w_i^{1,0,N} + e_i) \cdot (e_j + \nabla \tilde{w}_j^0) \\ &= \int_{I_N} A_{per} (\nabla w_i^{1,0,N} + e_i) \cdot (e_j + \nabla \tilde{w}_j^0) \\ &\quad + \int_Q C_{per} (\nabla w_i^{1,0,N} + e_i) \cdot (e_j + \nabla \tilde{w}_j^0). \end{aligned}$$

Next, using (3.19), we note that

$$\begin{aligned} \int_{I_N} A_{per} (\nabla w_i^{1,0,N} + e_i) \cdot (e_j + \nabla \tilde{w}_j^0) &= \int_{I_N} (\nabla w_i^{1,0,N} + e_i) \cdot A_{per}^T (e_j + \nabla \tilde{w}_j^0) \\ &= \int_{I_N} e_i \cdot A_{per}^T (e_j + \nabla \tilde{w}_j^0) \\ &= N^d \left(A_{per}^T\right)^* e_j \cdot e_i, \end{aligned}$$

and applying (2.4) to the periodic tensor A_{per}^T and noticing that $(A_{per}^T)^* = (A_{per}^*)^T$, we obtain

$$\int_{I_N} A_1^0(\nabla w_i^{1,0,N} + e_i)\cdot e_j = N^d A_{per}^* e_i \cdot e_j + \int_Q C_{per}(\nabla w_i^{1,0,N} + e_i)\cdot(e_j + \nabla \tilde{w}_j^0). \quad (3.20)$$

Since, by definition,

$$\begin{aligned} A_1^{*,N} e_i &= \int_{I_N} A_1^0(\nabla w_i^{1,0,N} + e_i) - \int_{I_N} A_{per}(\nabla w_i^0 + e_i) \\ &= \int_{I_N} A_1^0(\nabla w_i^{1,0,N} + e_i) - N^d A_{per}^* e_i, \end{aligned}$$

we deduce from (3.20) that

$$A_1^{*,N} e_i \cdot e_j = \int_Q C_{per}(\nabla w_i^{1,0,N} + e_i)\cdot(e_j + \nabla \tilde{w}_j^0). \quad (3.21)$$

We now define

$$q_i^{1,0,N} = w_i^{1,0,N} - w_i^0, \quad (3.22)$$

which solves

$$\begin{cases} -\operatorname{div}\left(A_1^0 \nabla q_i^{1,0,N}\right) = \operatorname{div}(\mathbb{1}_Q C_{per}(\nabla w_i^0 + e_i)) \quad \text{in } I_N, \\ q_i^{1,0,N} \ (N\mathbb{Z})^d - \text{periodic}. \end{cases} \quad (3.23)$$

We deduce from Lemma 6 of the appendix, applied to (3.23), that $\nabla q_i^{1,0,N}$ converges in $L^2_{loc}(\mathbb{R}^d)$, when $N \to +\infty$, to $\nabla q_i^{1,0,\infty}$, where $q_i^{1,0,\infty}$ is a $L^2_{loc}(\mathbb{R}^d)$ function solving

$$\begin{cases} -\operatorname{div}\left(A_1^0 \nabla q_i^{1,0,\infty}\right) = \operatorname{div}(\mathbb{1}_Q C_{per}(\nabla w_i^0 + e_i)) \quad \text{in } \mathbb{R}^d, \\ \nabla q_i^{1,0,\infty} \in L^2(\mathbb{R}^d). \end{cases} \quad (3.24)$$

Defining $w_i^{1,0,\infty} = w_i^0 + q_i^{1,0,\infty}$, it is clear that $\nabla w_i^{1,0,N}$ converges in $L^2(Q)$ to $\nabla w_i^{1,0,\infty}$. It follows from (3.21) that $A_1^{*,N} \underset{N\to+\infty}{\longrightarrow} \bar{A}_1^*$ with $\bar{A}_1^*$ defined by

$$\forall (i,j) \in [\![1,d]\!]^2, \ \ \bar{A}_1^* e_i \cdot e_j \ = \ \int_Q C_{per}(\nabla w_i^{1,0,\infty} + e_i)\cdot(e_j + \nabla \tilde{w}_j^0). \quad (3.25)$$

□

The computation of $\bar{A}_1^*$ requires to solve (3.24) which is defined in $\mathbb{R}^d$, but, in sharp contrast to the stochastic cell problems (3.4), is deterministic and has a right-hand side with compact support in $\mathbb{R}^d$. In practice, problem (3.24) is truncated on I_N. The following result gives insight on the truncation error.

Lemma 3. *Assume that $d \geq 3$ and that the unit cell Q contains an inclusion D, the boundary of which has regularity $\mathcal{C}^{1,\mu}$ for some $0 < \mu < 1$, and such that* $\operatorname{dist}(D, \partial Q) > 0$. *Assume also that A_{per} is Hölder continuous in $\overline{D}$ and in $\overline{Q \backslash D}$. Then there exists a tensor $B_1^{*,N}$, computed on I_N, and a constant K independent of N such that*

$$|B_1^{*,N} - \bar{A}_1^*| \leq K N^{-d}.$$

Proof. **Step 1.**

Fix (i,j) in $[\![1,d]\!]^2$. We first define the adjoint problem for (3.23), namely

$$\begin{cases} -\operatorname{div}\left((A_1^0)^T\nabla \tilde{q}_j^{1,0,N}\right) = \operatorname{div}(\mathbb{1}_Q C_{per}^T(\nabla \tilde{w}_j^0 + e_j)) \quad \text{in } I_N, \\ \tilde{q}_j^{1,0,N} \ (N\mathbb{Z})^d - \text{periodic}. \end{cases} \tag{3.26}$$

Applying Lemma 6 to (3.26), we also introduce the limit $\tilde{q}_j^{1,0,\infty}$ of $\tilde{q}_j^{1,0,N}$ when $N \to \infty$. It solves the adjoint problem of (3.24).

Then, using (3.26), we obtain

$$\begin{aligned} \int_Q C_{per}\nabla q_i^{1,0,N}\cdot(e_j+\nabla\tilde{w}_j^0) &= \int_{I_N} \nabla q_i^{1,0,N}\cdot \mathbb{1}_Q C_{per}^T(e_j+\nabla \tilde{w}_j^0) \\ &= -\int_{I_N}\nabla q_i^{1,0,N}\cdot (A_1^0)^T\nabla\tilde{q}_j^{1,0,N} \\ &= -\int_{I_N} A_1^0\nabla q_i^{1,0,N}\cdot\nabla\tilde{q}_j^{1,0,N}. \end{aligned}$$

Consequently, (3.21) and the definition (3.22) of $q_i^{1,0,N}$ yield

$$A_1^{*,N}e_i\cdot e_j = \int_Q C_{per}(\nabla w_i^0+e_i)\cdot(e_j+\nabla\tilde{w}_j^0) - \int_{I_N} A_1^0\nabla q_i^{1,0,N}\cdot\nabla\tilde{q}_j^{1,0,N}. \tag{3.27}$$

We know from Lemma 6 applied to (3.23) and (3.26) that $\mathbb{1}_{I_N}\nabla q_i^{1,0,N}$ and $\mathbb{1}_{I_N}\nabla\tilde{q}_j^{1,0,N}$converge strongly in $L^2(\mathbb{R}^d)$ to $\nabla q_i^{1,0,\infty}$ and $\nabla\tilde{q}_j^{1,0,\infty}$ respectively, when $N\to\infty$. Passing to the limit in (3.27) then gives

$$\bar{A}_1^* e_i\cdot e_j = \int_Q C_{per}(\nabla w_i^0+e_i)\cdot(e_j+\nabla\tilde{w}_j^0) - \int_{\mathbb{R}^d} A_1^0\nabla q_i^{1,0,\infty}\cdot\nabla\tilde{q}_j^{1,0,\infty}.$$

We now define $v_i^{1,0,N}$ and $\tilde{v}_j^{1,0,N}$ solutions to (3.23) and (3.26) with homogeneous Dirichlet (instead of periodic) boundary conditions on the boundary ∂I_N of I_N, and the tensor $B_1^{*,N}$ by

$$B_1^{*,N}e_i\cdot e_j = \int_Q C_{per}(\nabla w_i^0+e_i)\cdot(e_j+\nabla\tilde{w}_j^0) - \int_{I_N} A_1^0\nabla v_i^{1,0,N}\cdot\nabla\tilde{v}_j^{1,0,N}. \tag{3.28}$$

The proof of Proposition 2 is easily adapted to show that $B_1^{*,N}$ converges to A_1^* as N goes to infinity.

Step 2.

We consider

$$\left(B_1^{*,N}-\bar{A}_1^*\right)e_i\cdot e_j = \int_{\mathbb{R}^d} A_1^0\nabla q_i^{1,0,\infty}\cdot\nabla\tilde{q}_j^{1,0,\infty} - \int_{I_N} A_1^0\nabla v_i^{1,0,N}\cdot\nabla\tilde{v}_j^{1,0,N},$$

and expand the difference $B_1^{*,N}-\bar{A}_1^*$ as follows:

$$\begin{aligned} \left(B_1^{*,N}-\bar{A}_1^*\right)e_i\cdot e_j = &\int_{\mathbb{R}^d\setminus I_N} A_1^0\nabla q_i^{1,0,\infty}\cdot\nabla\tilde{q}_j^{1,0,\infty} \\ &+\left(\int_{I_N} A_1^0\nabla q_i^{1,0,\infty}\cdot\nabla\tilde{q}_j^{1,0,\infty} - \int_{I_N} A_1^0\nabla v_i^{1,0,N}\cdot\nabla\tilde{v}_j^{1,0,N}\right). \end{aligned} \tag{3.29}$$

We now show that the two terms in the right-hand side of (3.29) converge to 0 as N^{-d} when $N \to +\infty$.

We first note that the results of Lemma 8 of the appendix, stated for a $\mathbb{Z}^d$-periodic matrix, can be readily extended to address A_1^0 since A_1^0 is equal to A_{per} in $\mathbb{R}^d \backslash Q$.

We deduce from Lemma 7 applied to (3.24) that $q_i^{1,0,\infty}$ is defined uniquely up to an additive constant. Moreover, A_{per} being piecewise Hölder continuous, we deduce from Lemma 8 that there exists a unique solution to (3.24) which converges to zero at infinity.

Since we only use $\nabla q_i^{1,0,\infty}$ in $\bar{A}_1^*$, we can thus assume without loss of generality that $q_i^{1,0,\infty}$ converges to zero at infinity. Likewise, we assume that $\tilde{q}_j^{1,0,\infty}$ converges to zero at infinity.

We then deduce from Lemma 8 that there exists a constant K independent of N such that for $|x| \geq 1$,

$$|q_i^{1,0,\infty}(x)| \leq K|x|^{1-d}, \ |\tilde{q}_j^{1,0,\infty}(x)| \leq K|x|^{1-d}, \tag{3.30}$$

$$|\nabla q_i^{1,0,\infty}(x)| \leq K|x|^{-d}, \ |\nabla \tilde{q}_j^{1,0,\infty}(x)| \leq K|x|^{-d}, \tag{3.31}$$

$$|v_i^{1,0,N}(x)| \leq K|x|^{1-d}, \ |\tilde{v}_j^{1,0,N}(x)| \leq K|x|^{1-d}, \tag{3.32}$$

$$|\nabla v_i^{1,0,N}(x)| \leq K|x|^{-d}, \ |\nabla \tilde{v}_j^{1,0,N}(x)| \leq K|x|^{-d}. \tag{3.33}$$

Using (3.31), we have $\|\nabla q_i^{1,0,\infty}\|_{L^2(\mathbb{R}^d \backslash I_N)} \leq KN^{-d/2}$ and $\|\nabla \tilde{q}_j^{1,0,\infty}\|_{L^2(\mathbb{R}^d \backslash I_N)} \leq KN^{-d/2}$, and

$$\begin{aligned} \left| \int_{\mathbb{R}^d \backslash I_N} A_1^0 \nabla q_i^{1,0,\infty} \cdot \nabla \tilde{q}_j^{1,0,\infty} \right| &\leq \beta \|\nabla q_i^{1,0,\infty}\|_{L^2(\mathbb{R}^d \backslash I_N)} \|\nabla \tilde{q}_j^{1,0,\infty}\|_{L^2(\mathbb{R}^d \backslash I_N)} \\ &\leq KN^{-d}, \end{aligned} \tag{3.34}$$

where β is defined in (3.3).

We now address the second term of the right-hand side of (3.29) and write

$$\begin{aligned} &\int_{I_N} A_1^0 \nabla v_i^{1,0,N} \cdot \nabla \tilde{v}_j^{1,0,N} - \int_{I_N} A_1^0 \nabla q_i^{1,0,\infty} \cdot \nabla \tilde{q}_j^{1,0,\infty} \\ &\qquad = \int_{I_N} A_1^0 (\nabla v_i^{1,0,N} - \nabla q_i^{1,0,\infty}) \cdot \nabla \tilde{v}_j^{1,0,N} + \int_{I_N} A_1^0 \nabla q_i^{1,0,\infty} \cdot (\nabla \tilde{v}_j^{1,0,N} - \nabla \tilde{q}_j^{1,0,\infty}). \end{aligned}$$

Since $\operatorname{div}\left(A_1^0(\nabla v_i^{1,0,N} - \nabla q_i^{1,0,\infty})\right) = \operatorname{div}\left((A_1^0)^T(\nabla \tilde{v}_j^{1,0,N} - \nabla \tilde{q}_j^{1,0,\infty})\right) = 0$ in I_N, and $\tilde{v}_j^{1,0,N} = 0$ on ∂I_N, we have, using integration by parts,

$$\begin{aligned} \int_{I_N} A_1^0 (\nabla v_i^{1,0,N} - \nabla q_i^{1,0,\infty}) \cdot \nabla \tilde{v}_j^{1,0,N} &+ \int_{I_N} A_1^0 \nabla q_i^{1,0,\infty} \cdot (\nabla \tilde{v}_j^{1,0,N} - \nabla \tilde{q}_j^{1,0,\infty}) \\ &= \int_{\partial I_N} A_1^0 (\nabla v_i^{1,0,N} - \nabla q_i^{1,0,\infty}) \cdot \nu \, \tilde{v}_j^{1,0,N} \\ &\quad + \int_{\partial I_N} (A_1^0)^T (\nabla \tilde{v}_j^{1,0,N} - \nabla \tilde{q}_j^{1,0,\infty}) \cdot \nu \, q_i^{1,0,\infty} \\ &= \int_{\partial I_N} (A_1^0)^T (\nabla \tilde{v}_j^{1,0,N} - \nabla \tilde{q}_j^{1,0,\infty}) \cdot \nu \, q_i^{1,0,\infty}, \end{aligned}$$

where ν is the unit outward normal vector to ∂I_N.

The estimates (3.30) and (3.33) imply

$$\|q_i^{1,0,\infty}\|_{L^\infty(\partial I_N)} \leq K N^{1-d}, \quad \|(A_1^0)^T(\nabla \tilde{v}_j^{1,0,N} - \nabla \tilde{q}_j^{1,0,\infty}) \cdot \nu\|_{L^\infty(\partial I_N)} \leq K N^{-d},$$

while the measure of the boundary ∂I_N scales as N^{1-d}. Hence

$$\left| \int_{\partial I_N} (A_1^0)^T(\nabla \tilde{v}_j^{1,0,N} - \nabla \tilde{q}_j^{1,0,\infty}) \cdot \nu \, q_i^{1,0,\infty} \right| \leq K N^{-d},$$

and then

$$\left| \int_{I_N} A_1^0 \nabla v_i^{1,0,N} \cdot \nabla \tilde{v}_j^{1,0,N} - \int_{I_N} A_1^0 \nabla q_i^{1,0,\infty} \cdot \nabla \tilde{q}_j^{1,0,\infty} \right| \leq K N^{-d}. \tag{3.35}$$

We conclude by substituting (3.34) and (3.35) into (3.29).

□

Remark 4. *We assume $d \geq 3$ and piecewise Hölder regularity on A_{per}, and use Dirichlet boundary conditions in Lemma 3, because our proof relies on Lemma 8. Note however that the numerical experiments of Section 4 show, in dimension $d = 2$, that we again obtain the rate N^{-d} in the convergence of $A_1^{*,N}$ to $\bar{A}_1^*$ for two different A_{per}, one being piecewise Hölder continuous in the sense of Lemma 3 and the other not, and with periodic boundary conditions. Moreover, the explicit computations of Proposition 5 show that in dimension one, and without any assumption of regularity on A_1^0, the rate of convergence of $A_1^{*,N}$ to $\bar{A}_1^*$ is N^{-1}.*

3.4 Second-order term

For completeness, we state here the result regarding $A_2^{*,N}$ proved in [1]:

Proposition 4. *The sequence $A_2^{*,N}$ defined by (3.18) is bounded in $\mathbb{R}^{d\times d}$ and therefore converges up to extraction.*

We strongly believe that $A_2^{*,N}$ is actually a convergent sequence, as shown by our numerical tests thereafter. In fact, we even believe (see [1]) that we can write the expression of the limit. Note also that the explicit computations of Section 5.1 prove the convergence of $A_2^{*,N}$ in dimension one.

4 Numerical experiments

Our purpose in this section is to assess the approximation of A_η^* by the second-order expansion $A_{per}^* + \eta A_1^{*,N} + \eta^2 A_2^{*,N}$. The limited computational facilities we have access to impose that we restrict ourselves to the two-dimensional case. We first explain our general methodology and then make precise the specific settings.

4.1 Methodology

We will consider two commonly used composite materials as periodic reference materials A_{per}. The first material consists of a constant background reinforced by a periodic lattice of circular inclusions, that is

$$A_{per}(x_1, x_2) = 20 \times Id + 100 \sum_{k \in \mathbb{Z}^2} \mathbb{1}_{B(k,0.3)}(x_1, x_2) \times Id,$$

where $B(k, 0.3)$ is the ball of center k and radius 0.3. The second material is a laminate for which

$$A_{per}(x_1, x_2) = 20 \times Id + 100 \sum_{l \in \mathbb{Z}} \mathbb{1}_{l \leq x_1 \leq l+1}(x_1, x_2) \times Id.$$

In the case of material 1, the role of the perturbation is, loosely speaking, to randomly eliminate some fibers:

$$C_{per}(x_1, x_2) = -100 \sum_{k \in \mathbb{Z}^d} \mathbb{1}_{B(k,0.3)}(x_1, x_2) \times Id.$$

In the case of material 2, the perturbation consists in a random modification of the lamination direction:

$$C_{per}(x_1, x_2) = -100 \sum_{l \in \mathbb{Z}} \mathbb{1}_{l \leq x_1 \leq l+1}(x_1, x_2) \times Id + 100 \sum_{l \in \mathbb{Z}} \mathbb{1}_{l \leq x_2 \leq l+1}(x_1, x_2) \times Id.$$

In both cases, we have chosen the coefficients 20 and 100 in order to have a high contrast between A_{per} and $A_{per} + C_{per}$, and thus for the perturbation to be significant. There is of course nothing specific in the actual value of these coefficients.

These two materials are shown in Figure 3.

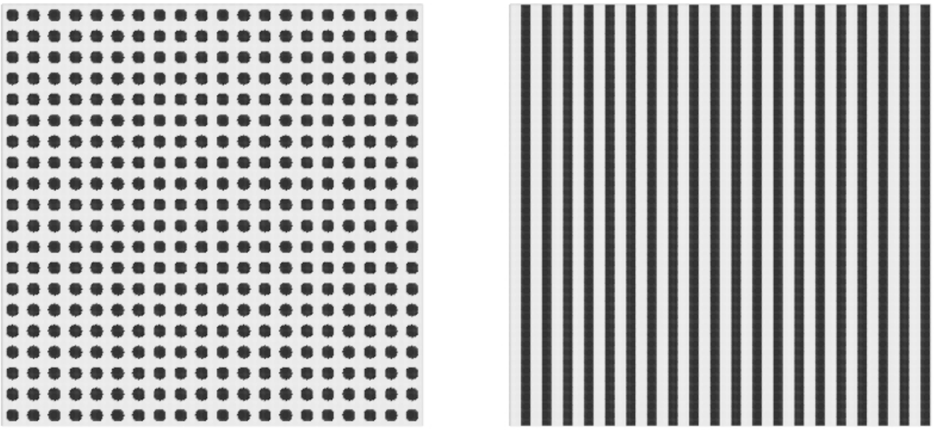

Figure 3: Left: a periodic lattice of circular inclusions. Right: a one-dimensional laminate.

Our goal is to compare A^*_η with its approximation $A^*_{per} + \eta A_1^{*,N} + \eta^2 A_2^{*,N}$ for each of these two particular settings. A major computational difficulty is the computation of the "exact" matrix A^*_η given by formula (3.5). It ideally requires to solve the stochastic cell problems (3.4) on $\mathbb{R}^d$. To this end we first use ergodicity and formulae (3.7) and (3.10), and actually compute, for a given realization ω and a domain I_N which is here equal to $[0, N]^2$ for convenience, $A^{*,N}_\eta(\omega)$ defined by

$$A^{*,N}_\eta(\omega) e_i = \frac{1}{N^d} \int_{I_N} A_\eta(x, \omega)(\nabla w_i^{\eta,N,\omega}(x) + e_i) dx. \tag{4.1}$$

In a second step, we take averages over the realizations ω.

For each ω, we use the finite element software FreeFem++ (available at www.freefem.org) to solve the boundary value problems (3.7) and compute the integrals (4.1). We work with standard P1 finite elements on a triangular mesh such that there are 10 degrees of freedom on each edge of the unit cell Q.

We define an approximate value $A_\eta^{*,N}$ as the average of $A_\eta^{*,N}(\omega)$ over 40 realizations ω. Our numerical experiments indeed show that the number 40 is sufficiently large for the convergence of the Monte-Carlo computation. We then let N grow from 5 to 80 by increments of 5. We observe that $A_\eta^{*,N}$ stabilizes at a fixed value around $N = 80$ and thus take $A_\eta^{*,80}$ as the reference value for A_η^* in our subsequent tests.

The next step is to compute the zero-order term A_{per}^*, and the first-order and second-order deterministic corrections $A_1^{*,N}$ and $A_2^{*,N}$. Using the same mesh and finite elements as for our reference computation above, we compute A_{per}^* using (2.3) and (2.4), and for each N we compute $A_1^{*,N}$ and $A_2^{*,N}$ using (3.17) and (3.18). We again let N grow from 5 to 80 by increments of 5 for $A_1^{*,N}$. The computation of $A_2^{*,N}$ being significantly more expensive (note that in (3.18) there is not only an integral over I_N but also a sum over the N^2 cells) we have to limit ourselves to $N = 25$ and approximate the value for N larger than 25 by the value obtained for $N = 25$.

Before presenting our results, we wish to discuss our expectations. Note that there are three distinct sources of error:

- the finite elements discretization error;
- the truncation error due to the replacement of $\mathbb{R}^d$ with I_N, in the computation of the stochastic cell problems (3.4) that are replaced with (3.7), as well as in the computation of the integrals (4.1);
- the stochastic error arising from the approximation of the expectation value (3.10) by an empirical mean.

The discretization error originates from the fact that, in practice, we only have access to the finite element approximations of all the functions manipulated here (such as w_i^0, $w_i^{\eta,N,\omega}$,...). Although we have not proved it in the specific context of our work, we believe, because it is shown in a similar weakly random setting (see [9]), that all the convergences stated here in the infinite-dimensional setting still hold true for the finite-dimensional approximations of the objects. Our numerical results indeed confirm it is the case. In order to eliminate the discretization error from the picture, our practical approach consists in adopting the *same* finite element space for all approximations of the cell and supercell problems, independently of N.

The truncation error is a different issue. For the "exact" computation of A_η^* (we mean not using the second-order expansion (3.15), but (4.1)), we use an empirical mean and a truncation. We know from [8], for a *continuous* notion of stationarity analogous to the *discrete* notion (2.8) we use here, and under mixing conditions which are satisfied in our setting, that the convergence of the truncated approximation to the ideal value holds at a rate $N^{-\kappa}$ with κ a non explicit function of the dimension, the mixing exponent and the coercivity constant of the material. On the other hand, in the second-order expansion (3.15), the zero-order term A_{per}^* is of course free of any truncation error. All that we know for the approximation $A_1^{*,N}$ defined by (3.17) to the first-order correction $\bar{A}_1^*$, is stated in Lemma 3 in dimension $d \geq 3$, under Hölder regularity assumptions on A_{per}, and with Dirichlet boundary conditions replacing periodic ones. One of the aims of our experiments is therefore to draw some numerical conclusions on the convergence of this term when these assumptions are not satisfied. Note that the matrices involved in our test materials are clearly discontinuous functions of x. The matrix corresponding to material 1 is piecewise Hölder continuous in the sense of Lemma 3, while the matrix corresponding to material 2 is not. As for the second-order approximation $A_2^{*,N}$, we have no insight on the truncation error and we also wish to study its convergence from a numerical point of view.

Finally, we have a practical approach to the stochastic error: besides the empirical mean, we provide, for each N, the minimum and the maximum values of $A_\eta^{*,N}(\omega)$ achieved over the 40 computations.

We now would like to emphasize that the purpose of our numerical tests is not to *prove* that

$$A_\eta^* = A_{per}^* + \eta A_1^{*,N} + \eta^2 A_2^{*,N} + o(\eta^2)$$

for a remainder term $o(\eta^2)$ that is independent of N, of the number of realizations and of the size of the mesh. Establishing experimentally that such an asymptotic holds is too demanding a task. It would indeed require letting η go to 0, which in turn, since we have to observe at least one (and in fact many) event per domain considered, would necessitate a supercell of size N extremely large. We cannot afford such a computational workload.

Using our numerical tests, we only hope here to demonstrate, and we indeed do so, that the second-order expansion is an approximation to A_η^* sufficiently good for all practical purposes, and in particular for η not too small ! We will observe that $A_2^{*,N}$ is not only bounded as stated in Proposition 4 but, as N goes to infinity, converges to a limit $\bar{A}_2^*$, and that both $A_1^{*,N}$ and $A_2^{*,N}$ converge to their respective limits faster than $A_\eta^{*,N}$ to A_η^* (which is intuitively expected since the former quantities are deterministic and contain less information). We will also observe that $A_{per}^* + \eta A_1^{*,N}$ is significantly closer to A_η^* than A_{per}^*, thereby motivating the expansion. The inclusion of the second-order term further improves the situation.

4.2 Results

In order to give an idea on how the perturbation affects the materials considered, we first show some typical realizations in Figure 4 and Figure 5. Our results are presented in Section 4.2.1 and Section 4.2.2 below. Since these results are qualitatively similar for the two materials, we comment on the results altogether in Section 4.2.3.

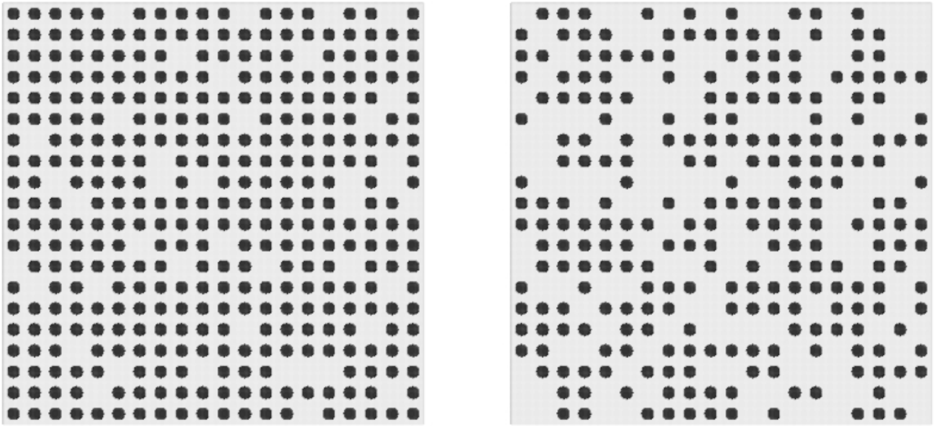

Figure 4: Two instances of material 1 with $\eta = 0.1$ (left) and $\eta = 0.4$ (right).

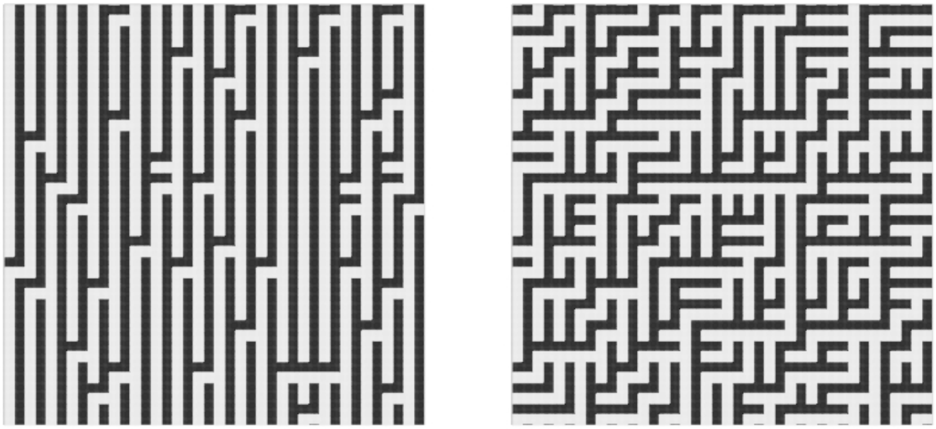

Figure 5: Two instances of material 2 with $\eta = 0.1$ (left) and $\eta = 0.5$ (right).

To present our numerical results, we choose the first diagonal entry $(1,1)$ of all the matrices considered. Other coefficients in the matrices behave qualitatively similarly. As mentioned in the previous Section, we illustrate a practical interval of confidence for our Monte-Carlo computation of A^*_η by showing, for each N, the minimum and maximum values of $A^{*,N}_\eta(\omega)$ achieved over the 40 realizations ω.

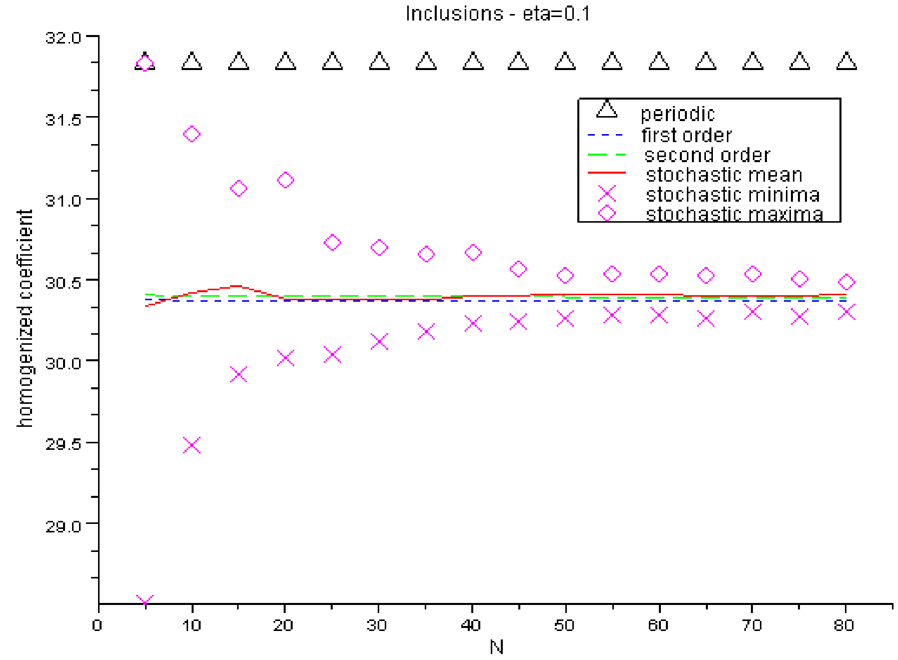
We will use the following legend in the graphs:

- *periodic*: gives the value of the periodic homogenized tensor A^*_{per};
- *first-order*: gives the value of $A^*_{per} + \eta A^{*,N}_1$;
- *second-order*: gives the value of $A^*_{per} + \eta A^{*,N}_1 + \eta^2 A^{*,N}_2$;
- *stochastic mean, minima and maxima*: respectively give the values of $A^{*,N}_\eta$ and the extrema obtained in the computation of the empirical mean.

Finally, the results are given for *some* specific values of η (not necessarily the same for both materials) which serve the purpose of testing our approach in a diversity of situations, from a “small” to a “not so small” perturbation.

4.2.1 Results for material 1

We show the results for $\eta = 0.1$, $\eta = 0.4$ and $\eta = 0.5$ (Figures 6, 7 and 8 respectively).



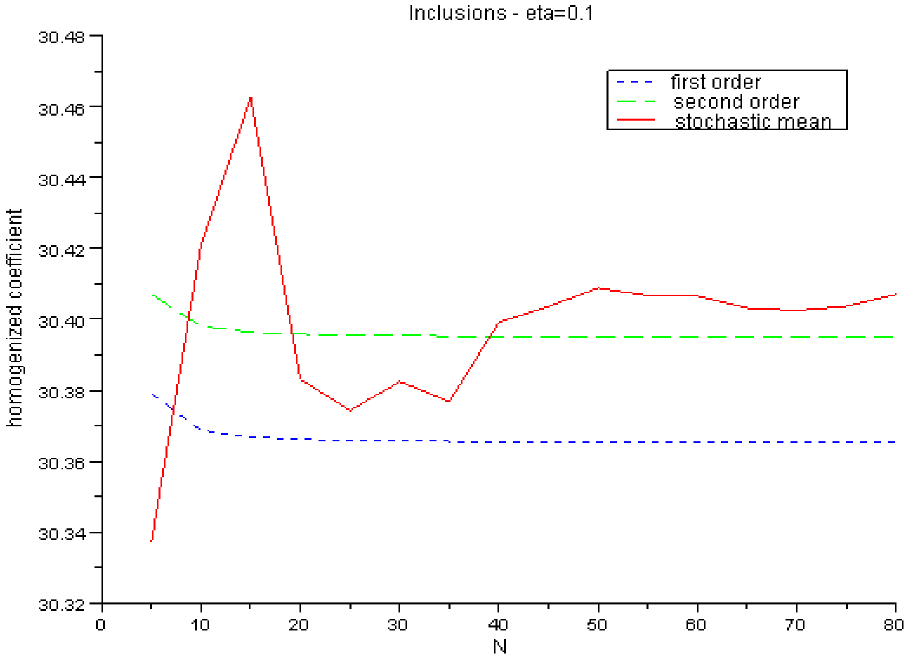


Figure 6: Results for material 1 and $\eta = 0.1$. Above: complete results. Below: close-up on $A_\eta^{*,N}$ and the first and second-order corrections.

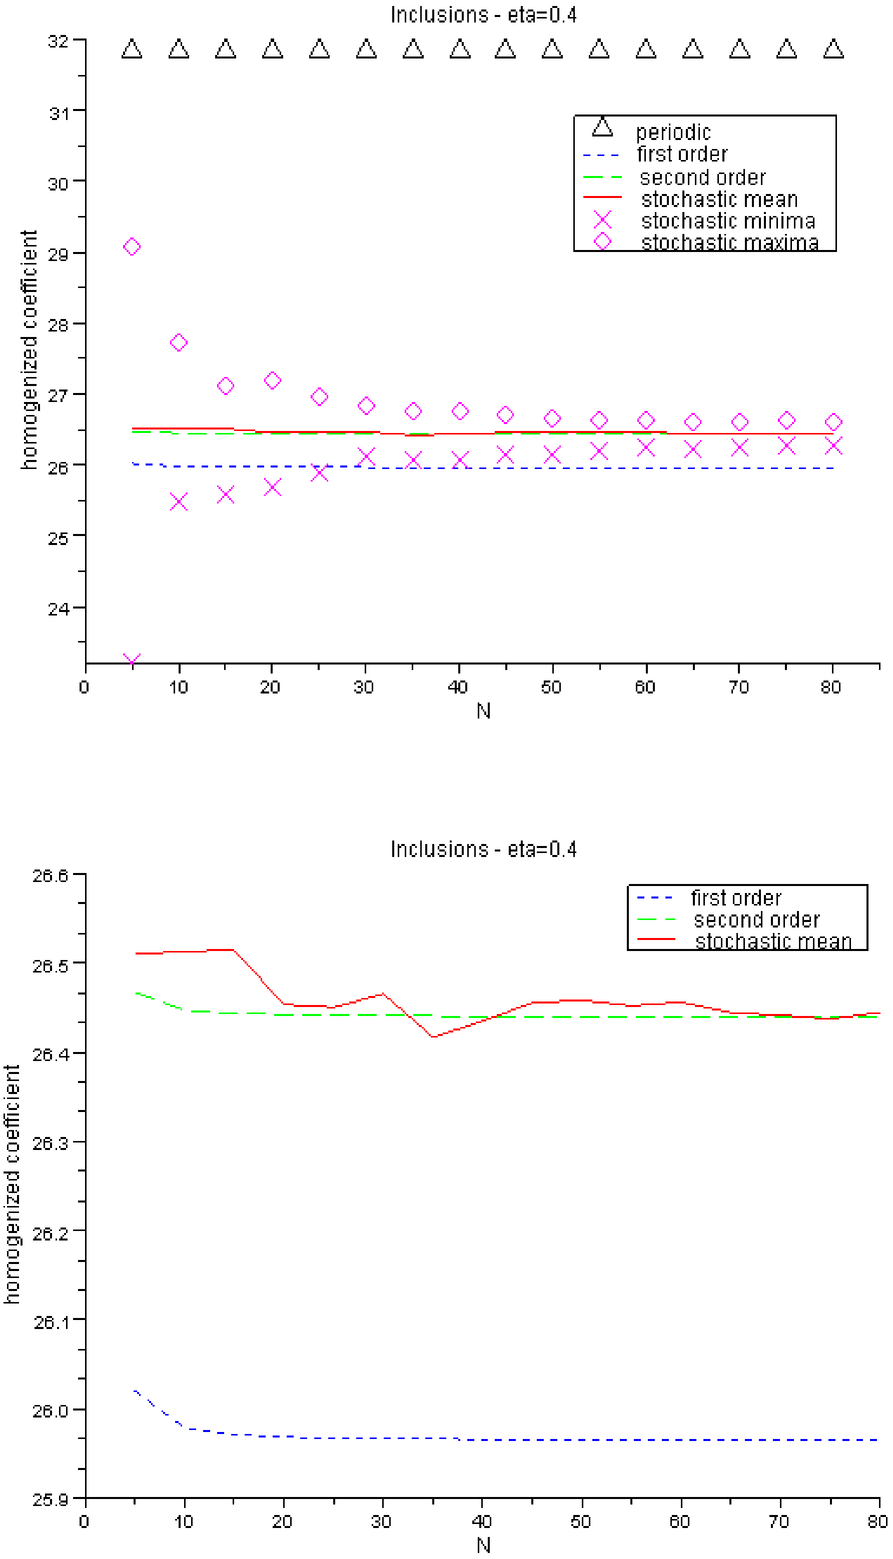

Figure 7: Results for material 1 and $\eta = 0.4$. Above: complete results. Below: close-up on $A_\eta^{*,N}$ and the first and second-order corrections.

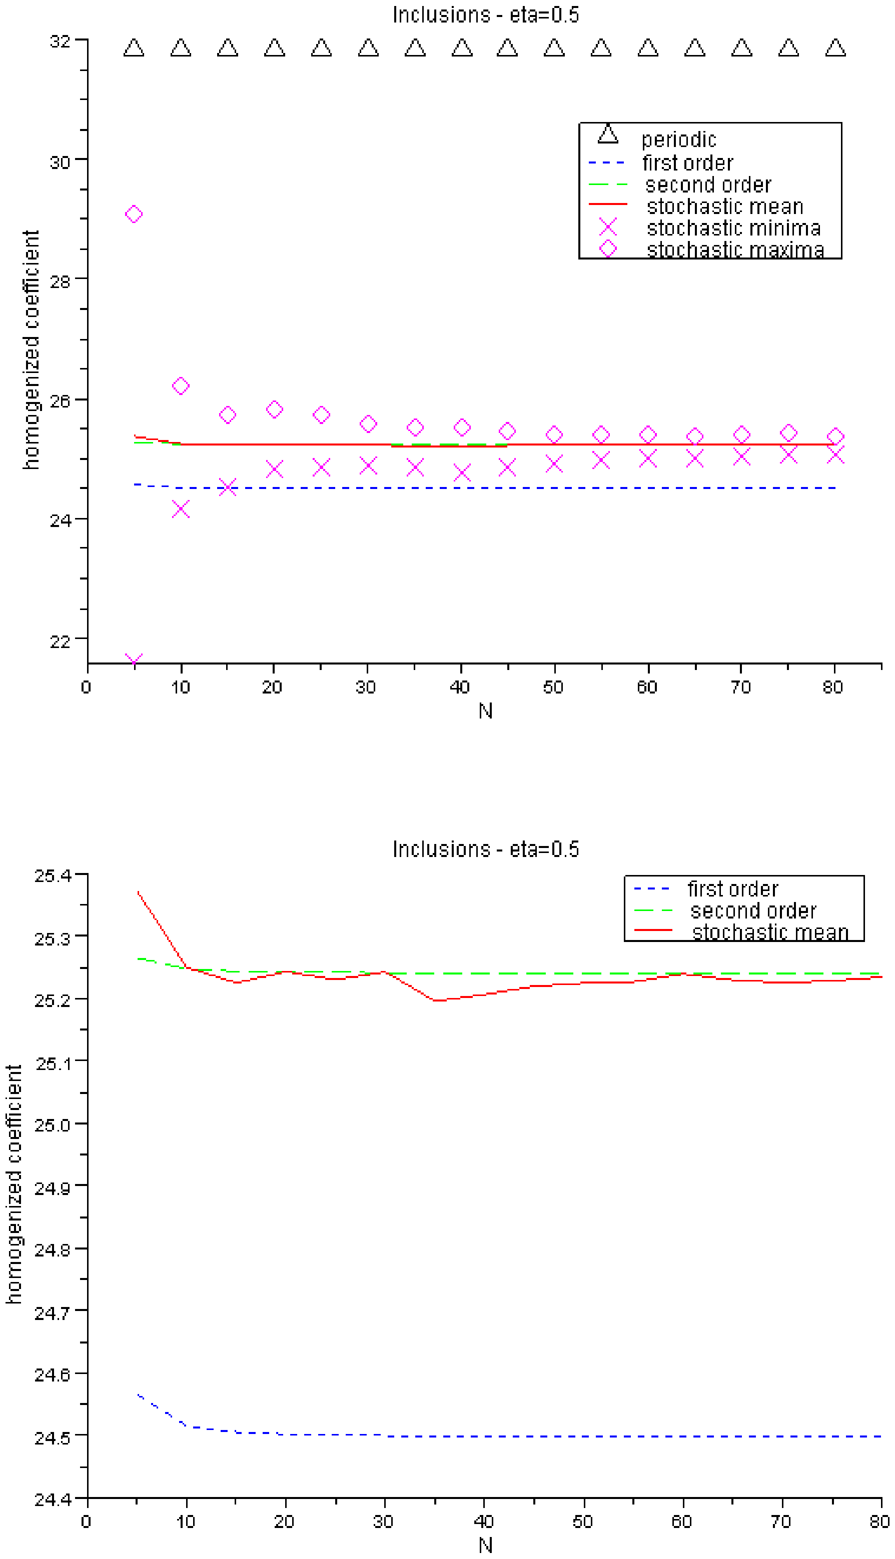

Figure 8: Results for material 1 and $\eta = 0.5$. Above: complete results. Below: close-up on $A_\eta^{*,N}$ and the first and second-order corrections.

4.2.2 Results for material 2

We now show for material 2 the results for $\eta = 0.1$, $\eta = 0.3$ and $\eta = 0.4$ (Figures 9, 10 and 11 respectively).

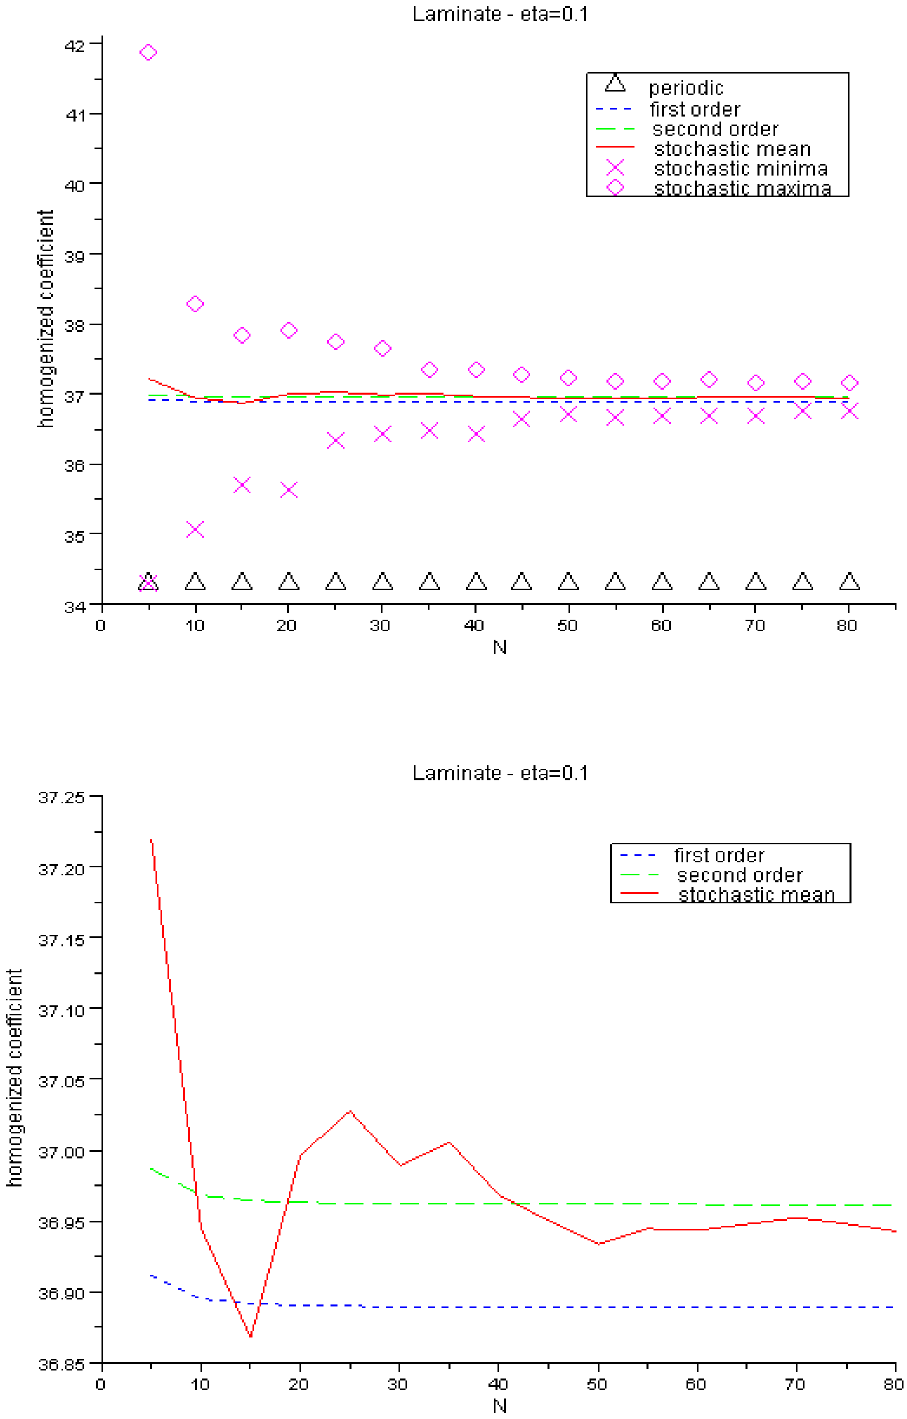

Figure 9: Results for material 2 and $\eta = 0.1$. Above: complete results. Below: zoom on $A_\eta^{*,N}$ and the first and second-order corrections.

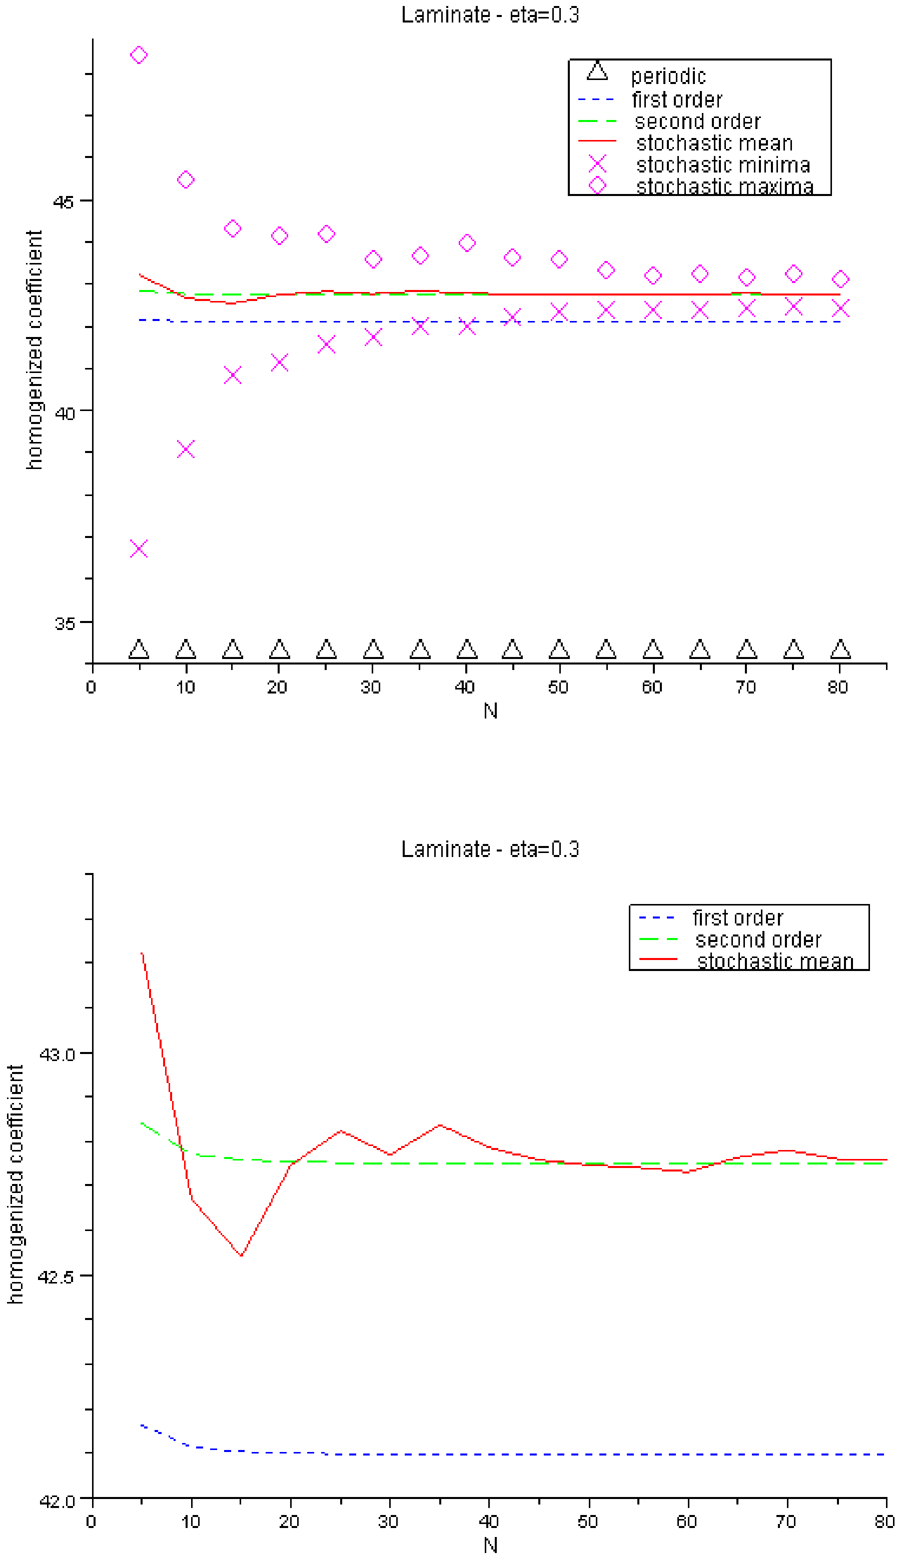

Figure 10: Results for material 2 and $\eta = 0.3$. Above: complete results. Below: zoom on $A_\eta^{*,N}$ and the first and second-order corrections.

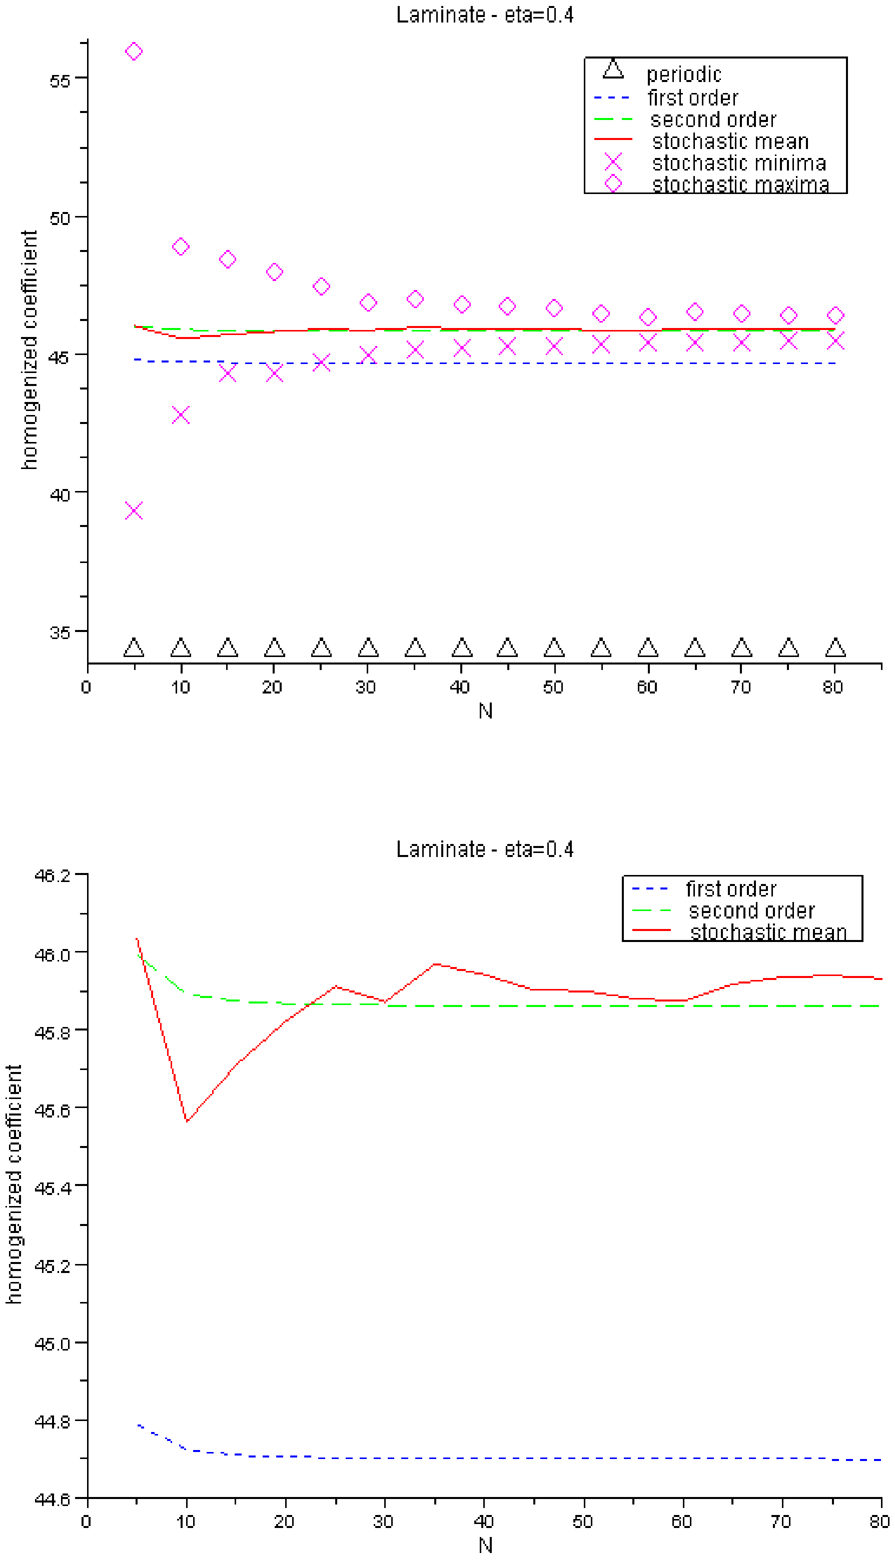

Figure 11: Results for material 2 and $\eta = 0.4$. Above: complete results. Below: zoom on $A^{*,N}_{\eta}$ and the first and second-order corrections.

4.2.3 Comments

Notice on the results for both materials (it is especially clear on the close-ups) that the first and second-order corrections $A_1^{*,N}$ and $A_2^{*,N}$ converge very fast in function of N, and in particular, as expected, much faster than the stochastic computation. Convergence of these deterministic computations is actually typically reached for $N = 10$.

Then, for all values of η, it is clear that the first-order correction enables to get substantially closer to A_η^*. The interest of the second-order term is also obvious as η gets larger, and we stress that the results are still excellent for η as large as 0.5, so that our approach is robust.

It is interesting to get some insight on the rate of convergence of the first-order correction, and to see whether the theoretical results of Lemma 3 still hold beyond the somewhat restrictive assumptions set in this lemma ($d \geq 3$, piecewise Hölder regularity on A_{per} and Dirichlet boundary conditions on ∂I_N). Recall that d is equal to 2 in our tests, and that $A_1^{*,N}$ is computed with periodic boundary conditions on the supercell I_N. Moreover, while the lattice of inclusions is piecewise Hölder continuous in the sense of Lemma 3 (meaning that there is an inclusion stricly contained in the unit cell Q and that the matrix A_{per} is Hölder continuous in each phase), the laminate is not.

We thus plot, for N going from 1 to 20 and for both materials, $\log(|(A_1^{*,N} - A_1^*)e_1 \cdot e_1|)$ in function of $\log(N)$. We recall that A_1^* is numerically given by $A_1^{*,80}$. For both materials the 20 points are arranged in a straight line (Figures 12 and 13). This leads us to perform a linear regression in order to obtain the slope of the lines. As regards material 1, we find a slope of -2.05 and a coefficient of correlation $R = 0.99$. For material 2, the slope is -1.9 with a coefficient of correlation equal to 0.95. The rate of convergence for both materials is then approximately $\mathcal{O}(N^{-d})$ with $d = 2$, which seems to indicate that the result of Lemma 3 still holds true in these circumstances.

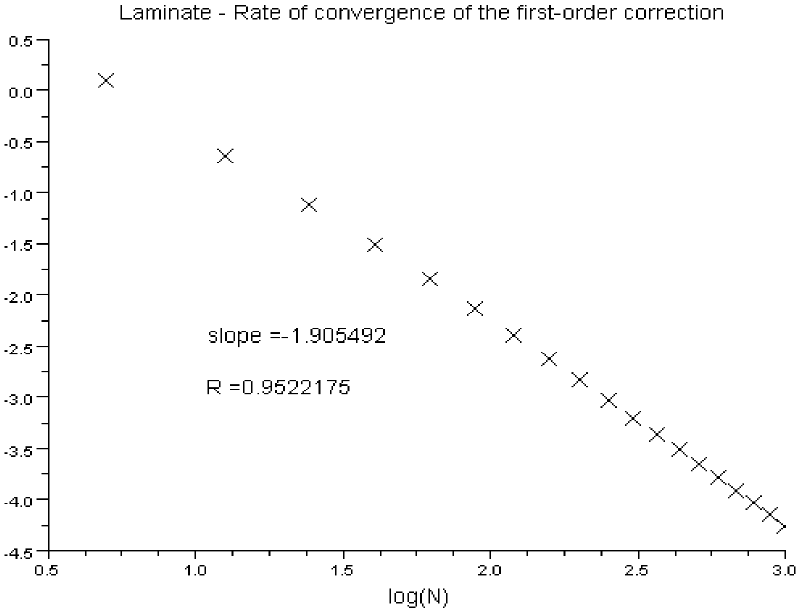

Figure 13: Rate of convergence of the first-order correction for material 2.

5 Appendix

The purpose of this appendix is two-fold. In Section 5.1 we prove that the approach exposed in Section 3, which relies on formal considerations for general dimensions, is rigorous in dimension $d = 1$. In Section 5.2, we prove for convenience of the reader some technical results used in Section 3.

5.1 One-dimensional computations

Although we are aware that homogenization theory is very specific in dimension 1, and can be somehow misleading by its simplicity, it is still important to check that our approach is rigorously founded in this setting. This is the aim of this section.

To stress that we work in dimension one, we use lower-case letters a_{per} and c_{per} instead of A_{per} and C_{per}, respectively, as well as for all the tensors manipulated.

We recall that in dimension one, a^*_{per} and a^*_η are given by the explicit expressions

$$a^*_{per} = \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{1}{a_{per}}\right)^{-1}, \quad a^*_\eta = \left(\mathbb{E}\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{1}{a_{per} + b_\eta c_{per}}\right)^{-1}.$$

This enables us to prove the following elementary result which shows that our approach is correct in dimension one:

Proposition 5. *In dimension $d = 1$, it holds*

$$a^*_\eta = a^*_{per} + \eta \bar{a}^*_1 + \eta^2 \bar{a}^*_2 + \mathcal{O}(\eta^3),$$

where $\bar{a}^*_1$ and $\bar{a}^*_2$ are the limits as $N \to \infty$ of $a^{*,N}_1$ and $a^{*,N}_2$ defined generally by (3.17) and (3.18) respectively.

Proof. We compute

$$
\begin{aligned}
(a^*_\eta)^{-1} &= \int_{-\frac{1}{2}}^{\frac{1}{2}} \left(\frac{1-\eta}{a_{per}} + \frac{\eta}{a_{per}+c_{per}} \right) \\
&= \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{1}{a_{per}} + \eta \int_{-\frac{1}{2}}^{\frac{1}{2}} \left(\frac{1}{a_{per}+c_{per}} - \frac{1}{a_{per}} \right) \\
&= (a^*_{per})^{-1} \left(1 - \eta a^*_{per} \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right).
\end{aligned}
$$

This yields the expansion

$$
\begin{aligned}
a^*_\eta = a^*_{per} &+ \eta (a^*_{per})^2 \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} + \eta^2 (a^*_{per})^3 \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right)^2 \\
&+ \eta^3 (a^*_{per})^4 \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right)^3 \left(1 - \eta a^*_{per} \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right)^{-1} \\
&= a^*_{per} + \eta (a^*_{per})^2 \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} + \eta^2 (a^*_{per})^3 \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right)^2 \\
&\qquad + \eta^3 (a^*_{per})^3 \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right)^3 a^*_\eta.
\end{aligned}
$$

It follows from (3.9) and (3.10) that the function $\eta \to a^*_\eta$ is bounded on $[0,1]$. Therefore

$$
\begin{aligned}
a^*_\eta =& a^*_{per} + \eta (a^*_{per})^2 \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \\
&+ \eta^2 (a^*_{per})^3 \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right)^2 + \mathcal{O}(\eta^3).
\end{aligned}
\tag{5.1}
$$

We now devote the rest of the proof to verifying that the coefficients of η and η^2 in (5.1) are indeed obtained as the limit as $N \to \infty$ of $a_1^{*,N}$ and $a_2^{*,N}$ generally defined by (3.17) and (3.18) respectively, in this particular one-dimensional setting.

The one-defect supercell solution $w^{1,0,N}$ generally defined by (3.12) satisfies here

$$
\begin{cases}
-\dfrac{d}{dx} \left(a_1^0 \left(\dfrac{d}{dx} w^{1,0,N} + 1 \right) \right) = 0 \quad \text{in }]-\dfrac{N}{2}, \dfrac{N}{2}[, \\
w^{1,0,N} \ N-\text{periodic}.
\end{cases}
$$

We easily compute

$$
\begin{aligned}
a_1^0 (\frac{d}{dx} w^{1,0,N} + 1) &= N \left(\int_{-\frac{N}{2}}^{\frac{N}{2}} \frac{1}{a_{per} + 1\!\!1_{[-\frac{1}{2},\frac{1}{2}]} c_{per}} \right)^{-1} \\
&= N \left(N (a^*_{per})^{-1} - \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right)^{-1} \\
&= a^*_{per} + \frac{(a^*_{per})^2}{N} \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} + \frac{(a^*_{per})^3}{N^2} \int_{-\frac{1}{2}}^{\frac{1}{2}} \left(\frac{c_{per}}{a_{per}(a_{per}+c_{per})} \right)^2 + o(N^{-2}).
\end{aligned}
$$

Thus $a_1^{*,N}$ defined generally by (3.17) takes here the form

$$a_1^{*,N} = \int_{-\frac{N}{2}}^{\frac{N}{2}} a_1^0(\frac{d}{dx}w^{1,0,N}+1) - Na_{per}^* = (a_{per}^*)^2 \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})} + o(1),$$

and

$$a_1^{*,N} \underset{N\to\infty}{\to} \bar{a}_1^* = (a_{per}^*)^2 \int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})}. \tag{5.2}$$

Likewise, for $k \in [\![-\frac{N-1}{2}, \frac{N-1}{2}]\!]$,

$$\begin{aligned} a_2^{0,k}(\frac{d}{dx}w^{2,0,k,N}+1) &= N\left(\int_{-\frac{N}{2}}^{\frac{N}{2}} \frac{1}{a_{per}+\mathbb{1}_{[-\frac{1}{2},\frac{1}{2}]\cup[k-\frac{1}{2},k+\frac{1}{2}]}c_{per}}\right)^{-1} \\ &= N\left(N(a_{per}^*)^{-1} - 2\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})}\right)^{-1} \\ = a_{per}^* + 2\frac{(a_{per}^*)^2}{N} \int_{-\frac{1}{2}}^{\frac{1}{2}} &\frac{c_{per}}{a_{per}(a_{per}+c_{per})} + 4\frac{(a_{per}^*)^3}{N^2} \int_{-\frac{1}{2}}^{\frac{1}{2}} \left(\frac{c_{per}}{a_{per}(a_{per}+c_{per})}\right)^2 + o(N^{-2}), \end{aligned}$$

which is independent of k (and so of the distance between the two defects). Hence, $a_2^{*,N}$ defined generally by (3.18) writes here

$$a_2^{*,N} = (a_{per}^*)^3 \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})}\right)^2 + o(1),$$

and

$$a_2^{*,N} \underset{N\to\infty}{\to} \bar{a}_2^* = (a_{per}^*)^3 \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \frac{c_{per}}{a_{per}(a_{per}+c_{per})}\right)^2. \tag{5.3}$$

Using (5.1), (5.2) and (5.3), we verify that

$$a_\eta^* = a_{per}^* + \eta\bar{a}_1^* + \eta^2\bar{a}_2^* + \mathcal{O}(\eta^3).$$

□

Remark 5. *The fact that the distance between two defects does not play a role in the computation of $a_2^{*,N}$ is of course specific to the one-dimensional setting. As we have seen, this is not true in higher dimensions where the geometry comes into play.*

5.2 Some technical lemmas

The second part of this appendix is different in nature. We prove here three technical lemmas that are useful for our proofs in Section 3. These results, or related ones, are probably well known and part of the mathematical literature. We prove them here under specific assumptions for the convenience of the reader and for consistency. We acknowledge several instructive discussions with Xavier Blanc on the content of this section.

We recall that $Q = [-\frac{1}{2}, \frac{1}{2}]^d$ and $I_N = [-\frac{N}{2}, \frac{N}{2}]^d$.

Lemma 6. *Consider $f \in L^2(Q)$, and a tensor field A from $\mathbb{R}^d$ to $\mathbb{R}^{d\times d}$ such that there exist $\lambda > 0$ and $\Lambda > 0$ such that*

$$\forall \xi \in \mathbb{R}^d,\ \text{a.e in } x \in \mathbb{R}^d,\ \lambda|\xi|^2 \leq A(x)\xi \cdot \xi \text{ and } |A(x)\xi| \leq \Lambda|\xi|.$$

Consider q^N solution to

$$\begin{cases} -\operatorname{div}\left(A\nabla q^N\right) = \operatorname{div}(\mathbb{1}_Q f) & \text{in } I_N, \\ q^N\ (N\mathbb{Z})^d - \text{periodic.} \end{cases} \tag{5.4}$$

Then $\mathbb{1}_{I_N}\nabla q^N$ converges in $L^2(\mathbb{R}^d)$, when N goes to infinity, to ∇q^∞, where q^∞ is a $L^2_{loc}(\mathbb{R}^d)$ function solving

$$\begin{cases} -\operatorname{div}\left(A\nabla q^\infty\right) = \operatorname{div}(\mathbb{1}_Q f) & \text{in } \mathbb{R}^d, \\ \nabla q^\infty \in L^2(\mathbb{R}^d). \end{cases} \tag{5.5}$$

Proof. We first obtain a bound on $\|\nabla q^N\|_{L^2(I_N)}$ and then, by compactness, extract a limit of this sequence.

Multiplying the first line of (3.23) by q^N and integrating by parts yields

$$\int_{I_N} A\nabla q^N \cdot \nabla q^N = -\int_Q f \cdot \nabla q^N, \tag{5.6}$$

from which we deduce

$$\|\nabla q^N\|_{L^2(I_N)} \leq \frac{1}{\lambda}\|f\|_{L^2(Q)}. \tag{5.7}$$

Consider now a bounded domain $\mathcal{D} \subset \mathbb{R}^d$. For N sufficiently large, we have $\mathcal{D} \subset I_N$ and so

$$\|\nabla q^N\|_{L^2(\mathcal{D})} \leq \frac{1}{\lambda}\|f\|_{L^2(Q)}.$$

Thus ∇q^N is bounded in $L^2(\mathcal{D})$ for every bounded subset $\mathcal{D} \subset \mathbb{R}^d$.

Using diagonal extraction and the weak compactness of $L^2_{loc}(\mathbb{R}^d)$, we can classically find a subsequence of ∇q^N such that, without changing the notation for simplicity,

$$\nabla q^N \rightharpoonup h \quad \text{weakly in } L^2_{loc}(\mathbb{R}^d). \tag{5.8}$$

We deduce from (5.7) and (5.8) that for every bounded subset $\mathcal{D} \subset \mathbb{R}^d$,

$$\|h\|_{L^2(\mathcal{D})} \leq \frac{1}{\lambda}\|f\|_{L^2(Q)}.$$

This implies that the vector h is in $L^2(\mathbb{R}^d)$.

We also deduce from (5.8) that for all $(i,j) \in [\![1,d]\!]^2$, $\frac{\partial h_j}{\partial x_i} = \frac{\partial h_i}{\partial x_j}$. This implies that h is the gradient of a function we call q^∞. Since $h \in L^2(\mathbb{R}^d)$, $\nabla q^\infty = h$ is in $L^2(\mathbb{R}^d)$ and q^∞ in $L^2_{loc}(\mathbb{R}^d)$.

Finally, (5.8) yields that ∇q^N converges to ∇q^∞ in $\mathcal{D}'(\mathbb{R}^d)$. We can then pass to the limit $N \to \infty$ in the first line of (5.4) and obtain

$$-\operatorname{div}\left(A\nabla q^\infty\right) = \operatorname{div}(\mathbb{1}_Q f) \quad \text{in } \mathbb{R}^d$$

in the sense of distributions.

We have proved that ∇q^N converges up to extraction and weakly in $L^2_{loc}(\mathbb{R}^d)$ to ∇q^∞, where q^∞ is in $L^2_{loc}(\mathbb{R}^d)$ and solves

$$\begin{cases} -\operatorname{div}(A\nabla q^\infty) = \operatorname{div}(\mathbb{1}_Q f) \quad \text{in } \mathbb{R}^d, \\ \nabla q^\infty \in L^2(\mathbb{R}^d). \end{cases} \tag{5.9}$$

We deduce from Lemma 7 thereafter that (5.9) has a solution unique up to an additive constant, so that ∇q^∞ is uniquely defined. A classical compactness argument then yields that the whole sequence ∇q^N converges weakly to ∇q^∞ in $L^2_{loc}(\mathbb{R}^d)$.

It is clear from what precedes that

$$\mathbb{1}_{I_N} \nabla q^N \rightharpoonup \nabla q^\infty \quad \text{weakly in } L^2(\mathbb{R}^d). \tag{5.10}$$

We now prove that the sequence $\mathbb{1}_{I_N}\nabla q^N$ actually converges strongly to ∇q^∞ in $L^2(\mathbb{R}^d)$.

Using a cut-off technique as in the proof of Lemma 7 thereafter, we deduce from (5.5) that

$$\int_{\mathbb{R}^d} A\nabla q^\infty \cdot \nabla q^\infty = -\int_Q f \cdot \nabla q^\infty. \tag{5.11}$$

The weak convergence of ∇q^N to ∇q^∞ implies that the right-hand side of (5.6) converges to the right-hand side of (5.11). Consequently,

$$\int_{I_N} A\nabla q^N \cdot \nabla q^N \to \int_{\mathbb{R}^d} A\nabla q^\infty \cdot \nabla q^\infty, \tag{5.12}$$

and, denoting by A_s the symmetric part of A, (5.12) is equivalent to

$$\int_{I_N} A_s\nabla q^N \cdot \nabla q^N \to \int_{\mathbb{R}^d} A_s\nabla q^\infty \cdot \nabla q^\infty. \tag{5.13}$$

A_s is of course a uniformly coercive tensor field, we can thus define its square root $A_s^{1/2}$. It follows from (5.13) that

$$\|A_s^{1/2}\mathbb{1}_{I_N}\nabla q^N\|_{L^2(\mathbb{R}^d)} \to \|A_s^{1/2}\nabla q^\infty\|_{L^2(\mathbb{R}^d)}. \tag{5.14}$$

On the other hand, multiplying (5.10) by $A_s^{1/2}$, we obtain

$$A_s^{1/2}\mathbb{1}_{I_N}\nabla q^N \rightharpoonup A_s^{1/2}\nabla q^\infty \quad \text{weakly in } L^2(\mathbb{R}^d). \tag{5.15}$$

Because of the uniform convexity of $L^2(\mathbb{R}^d)$, it is well known that (5.14) and (5.15) imply

$$A_s^{1/2}\mathbb{1}_{I_N}\nabla q^N \to A_s^{1/2}\nabla q^\infty \quad \text{strongly in } L^2(\mathbb{R}^d). \tag{5.16}$$

Multiplying (5.16) by $A_s^{-1/2}$, we finally have

$$\mathbb{1}_{I_N}\nabla q^N \to \nabla q^\infty \quad \text{strongly in } L^2(\mathbb{R}^d). \tag{5.17}$$

□

Lemma 7. *Let A be a tensor field from $\mathbb{R}^d$ to $\mathbb{R}^{d\times d}$ such that there exist $\lambda > 0$ and $\Lambda > 0$ such that*

$$\forall \xi \in \mathbb{R}^d,\ \text{a.e in } x \in \mathbb{R}^d,\ \lambda|\xi|^2 \le A(x)\xi\cdot\xi \text{ and } |A(x)\xi| \le \Lambda|\xi.$$

Consider $u \in L^2_{loc}(\mathbb{R}^d)$ solving

$$\begin{cases} -\operatorname{div}(A\nabla u) = 0 & \text{in } \mathbb{R}^d,\\ \nabla u \in L^2(\mathbb{R}^d). \end{cases} \tag{5.18}$$

Then u is constant.

Proof. We define a smooth cut-off function $\chi \in C^\infty(\mathbb{R}^d)$ such that $\chi = 1$ in the ball B_R, $\chi = 0$ in $\mathbb{R}^d \backslash B_{2R}$ and $\|\nabla\chi\|_{L^\infty(\mathbb{R}^d)} \le 2/R$.

Multiplying the first line of (5.18) by χu and integrating by parts, we obtain

$$\int_{\mathbb{R}^d} A\nabla u\cdot(\nabla u)\,\chi = -\int_{\mathbb{R}^d} A\nabla u\cdot(\nabla\chi)\,u.$$

Using the Cauchy-Schwarz inequality, this yields

$$\begin{aligned}\int_{B_R}|\nabla u|^2 &\le \frac{\Lambda}{\lambda}\|\nabla\chi\|_{L^\infty(\mathbb{R}^d)}\left(\int_{B_{2R}\backslash B_R}|\nabla u|^2\right)^{1/2}\left(\int_{B_{2R}\backslash B_R}|u|^2\right)^{1/2}\\ &\le \frac{2\Lambda}{R\lambda}\left(\int_{B_{2R}\backslash B_R}|\nabla u|^2\right)^{1/2}\left(\int_{B_{2R}\backslash B_R}|u|^2\right)^{1/2}.\end{aligned} \tag{5.19}$$

Defining

$$u_R = \frac{1}{|B_{2R}\backslash B_R|}\int_{B_{2R}\backslash B_R} u,$$

it is clear that $u - u_R$ is also a solution to (5.18) so that the above computations are valid for $u - u_R$. Since $\nabla(u-u_R) = \nabla u$, we deduce from (5.19) that

$$\int_{B_R}|\nabla u|^2 \le \frac{2\Lambda}{R\lambda}\left(\int_{B_{2R}\backslash B_R}|\nabla u|^2\right)^{1/2}\left(\int_{B_{2R}\backslash B_R}|u-u_R|^2\right)^{1/2}. \tag{5.20}$$

We next apply the Poincaré-Wirtinger inequality to $u - u_R$ on $B_{2R}\backslash B_R$. There exists a constant $C(R)$ which depends only on R such that

$$\int_{B_{2R}\backslash B_R}|u-u_R|^2 \le C(R)\int_{B_{2R}\backslash B_R}|\nabla u|^2.$$

An easy scaling argument shows that $C(R)$ is equal to R times the Poincaré-Wirtinger constant on $B_2\backslash B_1$, so that there exists a constant C such that

$$\int_{B_{2R}\backslash B_R}|u-u_R|^2 \le CR\int_{B_{2R}\backslash B_R}|\nabla u|^2. \tag{5.21}$$

We deduce from (5.20) and (5.21) that

$$\int_{B_R}|\nabla u|^2 \le \frac{2C\Lambda}{\lambda}\int_{B_{2R}\backslash B_R}|\nabla u|^2. \tag{5.22}$$

Since $\nabla u \in L^2(\mathbb{R}^d)$, the left-hand side of (5.22) converges to $\int_{\mathbb{R}^d}|\nabla u|^2$ when $R\to\infty$, and the right-hand side of (5.22) converges to 0. Then $\nabla u = 0$ and u is a constant. $\square$

Lemma 8. *For $d \geq 3$, consider a $\mathbb{Z}^d$-periodic tensor field A such that there exist $\lambda > 0$ and $\Lambda > 0$ such that*

$$\forall \xi \in \mathbb{R}^d,\ \text{a.e in } x \in \mathbb{R}^d,\ \lambda|\xi|^2 \leq A(x)\xi \cdot \xi \text{ and } |A(x)\xi| \leq \Lambda|\xi.$$

Assume that the unit cell Q contains an inclusion D, the boundary of which has regularity $\mathcal{C}^{1,\mu}$ for some $0 < \mu < 1$, and such that $\operatorname{dist}(D, \partial Q) > 0$. *Assume also that A_{per} is Hölder continuous in $\overline{D}$ and in $\overline{Q \backslash D}$.*

Let f be a function in $L^2(Q)$.

There exists a unique solution $u \in L^2_{loc}(\mathbb{R}^d)$ to

$$\begin{cases} -\operatorname{div}(A\nabla u) = \operatorname{div}(\mathbb{1}_Q f) & \text{in } \mathbb{R}^d, \\ \nabla u \in L^2(\mathbb{R}^d),\ \lim\limits_{|x|\to\infty} u(x) = 0. \end{cases} \tag{5.23}$$

Defining also u_0 the unique solution to

$$\begin{cases} -\operatorname{div}(A\nabla u_0) = \operatorname{div}(\mathbb{1}_Q f) & \text{in } \mathcal{O}, \\ u_0 \in H^1_0(\mathcal{O}), \end{cases} \tag{5.24}$$

where $\mathcal{O}$ is a bounded domain of $\mathbb{R}^d$ containing Q and such that $\operatorname{dist}(\partial\mathcal{O}, Q) > 1$, *there exists a constant K which depends only on λ, Λ, μ, d, f and the Hölder exponents, and* not *on the domain, such that for $|x| \geq 1$, it holds*

$$|u_0(x)| \leq \frac{K}{|x|^{d-1}}, \quad |\nabla u_0(x)| \leq \frac{K}{|x|^d},$$

$$|u(x)| \leq \frac{K}{|x|^{d-1}}, \quad |\nabla u(x)| \leq \frac{K}{|x|^d}.$$

Proof. Let G_0 be the Green kernel associated with A with homogeneous Dirichlet boundary conditions on $\partial\mathcal{O}$, uniquely defined by

$$\begin{cases} -\operatorname{div}(A\nabla G_0(\cdot, y)) = \delta_y & \text{in } \mathcal{O}, \\ G_0(\cdot, y) \in W^{1,1}_0(\mathcal{O}), \end{cases}$$

and G be the Green kernel associated with A on $\mathbb{R}^d$, unique solution to

$$\begin{cases} -\operatorname{div}(A\nabla G(\cdot, y)) = \delta_y & \text{in } \mathbb{R}^d, \\ G(\cdot, y) \in W^{1,1}_{loc}(\mathbb{R}^d) \cap H^1(\mathbb{R}^d \backslash B(y, 1)). \end{cases}$$

We deduce from arguments stated in [6, Lemma 4.2] and relying on [10, Theorem 3.3], and on [5, Lemma 16] when A is Hölder continuous and [13, Theorem 1.9] when A is piecewise Hölder continuous, that there exists a constant K depending only on λ, Λ, μ, d and the Hölder exponents, and not on the domain, such that

$$\forall (x, y) \in \mathcal{O},\ |\nabla_y G_0(x, y)| \leq \frac{K}{|x - y|^{d-1}}, \quad |\nabla_x \nabla_y G_0(x, y)| \leq \frac{K}{|x - y|^d}, \tag{5.25}$$

$$\forall (x, y) \in \mathbb{R}^d,\ |\nabla_y G(x, y)| \leq \frac{K}{|x - y|^{d-1}}, \quad |\nabla_x \nabla_y G(x, y)| \leq \frac{K}{|x - y|^d}. \tag{5.26}$$

It is well known that u_0 solution to (5.24) can be represented as

$$u_0(x) = \int_{\mathcal{O}} G_0(x,y)\mathrm{div}(\mathbb{1}_Q f)(y)dy. \tag{5.27}$$

It is also clear that the function $\tilde{u}$ defined by

$$\tilde{u}(x) = \int_{\mathbb{R}^d} G(x,y)\mathrm{div}(\mathbb{1}_Q f)(y)dy \tag{5.28}$$

is a $H^1_{loc}(\mathbb{R}^d)$ function which satisfies

$$-\mathrm{div}\,(A\nabla\tilde{u}) = \mathrm{div}\,(\mathbb{1}_Q f)$$

in the sense of distributions.

Integrating by parts in (5.27) and (5.28) for $x \notin Q$, we have

$$u_0(x) = \int_Q \nabla_y G_0(x,y)\cdot f(y)dy, \quad \tilde{u}(x) = \int_Q \nabla_y G(x,y)\cdot f(y)dy, \tag{5.29}$$

and then

$$\nabla u_0(x) = \int_Q \nabla_x\nabla_y G_0(x,y)\cdot f(y)dy, \quad \nabla\tilde{u}(x) = \int_Q \nabla_x\nabla_y G(x,y)\cdot f(y)dy. \tag{5.30}$$

Using estimates (5.25) and (5.26) in (5.29) and (5.30) respectively, we find that there exists a constant K depending only on λ, Λ, μ, d, f and the Hölder exponents, and not on the domain, such that for $|x| \geq 1$, we have

$$|u_0(x)| \leq \frac{K}{|x|^{d-1}} \quad \text{and} \quad |\nabla u_0(x)| \leq \frac{K}{|x|^d}, \tag{5.31}$$

$$|\tilde{u}(x)| \leq \frac{K}{|x|^{d-1}} \quad \text{and} \quad |\nabla\tilde{u}(x)| \leq \frac{K}{|x|^d}. \tag{5.32}$$

The function $\tilde{u}$ being in $H^1_{loc}(\mathbb{R}^d)$, we deduce from (5.32) that $\nabla\tilde{u} \in L^2(\mathbb{R}^d)$. Consequently, $\tilde{u}$ solves

$$\begin{cases} -\,\mathrm{div}\,(A\nabla\tilde{u}) = \mathrm{div}\,(\mathbb{1}_Q f) & \text{in } \mathbb{R}^d, \\ \nabla\tilde{u} \in L^2(\mathbb{R}^d). \end{cases} \tag{5.33}$$

We know from Lemma 7 that (5.33) has a solution unique up to an additive constant. It follows from (5.32) that $\tilde{u}$ converges to zero at infinity, so that $\tilde{u} = u$ unique solution to (5.23).
